After Bill Sabin's response I am so keen to see the punch line for
this that I want to ask with an example I can understand.

Suppose I plug a transmission line terminated by something I'm unaware
of into my amplifier and turn it on. At the amplifier output terminal I
measure a voltage of 80V, a current of 1.6A and a phase angle of 36.9
degrees between them. I can immediately tell that the amplifier is
delivering about 102W to its load. If I know Z0 of the transmission line
is 50 ohms I might also be able to deduce that the VSWR is about 2:1, the
forward power is about 115W and the reflected power is about 13W, but
there doesn't seem to be any way for the amplifier to know this.

Suppose I now turn off the amplifier, unplug the transmission line and
replace it with lumped components with an impedance of 40+j30 ohms tied
directly to the amplifer output terminal. I turn the amplifier back on
and at the output terminal measure a voltage of 80V, a current of 1.6A
and a phase angle of 36.9 degrees between them. I can tell that the
amplifer is again delivering about 102W to the load.

Is there any possible way, from inside the amplifier, to tell any
difference at all between these two cases in the steady state? If the
amplifier "sees" Z0 in the first case isn't it seeing something that
doesn't exist in the second case? If I didn't tell you the transmission
line Z0 was 50 ohms in the first case, how could you have even determined
that this was what the amplifier was "seeing" from the only conditions
visible inside the amplifier (i.e. the voltage and current at its output
terminals)?

It seems to me that Bill Sabin must be precisely correct. The amplifier
can't "know" whether this is a transmission line problem or not from
anything that is measureable at its output. It can't determine Z0 from
anything it can see at the terminals in steady state, and if Z0 is
irrelevant to the operation of the amplifier then how could voltage
and current "waves" matter to it?

>From the perspective of the internal components in the amplifier, there are
>two "sources" in the system. One is the internal amplifier forward driving
>source and the other is the rearward driving source created from the
>reflections that arrive at the amplifier output. In all cases, except where
>the amplifier has a purely reactive output impedance, some level of voltage
>and current travel rearward into the amplifier.

The amplifier sees 80V and 1.6A out of phase by 36.9 degrees at its
output terminals. These are scalar (or phasor) voltage and current
values, they aren't "travelling" anywhere. It can't "see" Z0 in steady
state as far as I can tell, or distinguish a transmission line problem
from a circuit problem, so how could the distinction possibly matter to
its operation? Where's this other "source" when it is lumped components
instead of the transmission line?

I understand that amplifiers will run at higher output currents and/or
voltages higher when delivering power to loads other than their nominal
design output impedance, and that this may cause them to run less
efficiently or even suffer damage. This is what Bill Sabin said. I'm
still willing to believe there is something more to know about this
but I'm really not getting what it is.

Thanks,
Dennis Ferguson

Speaking of Force 12, I just received their catalog today! I was
blown away! Its not a standard item/price book. It is actually
educational!

Anyway, people have been talking about verticles in this thread. I
Highly and inthusiastically suggest you check out Force 12's V-3 or ZR-3!

I have no opinions as I have not operated this antenna. BUT, I'm
impressed with what I've read and the opinion of AA6PW who has run
Force 12 antennas.

They deserve a look!

Check out any serious aircraft and you'll find what look like little
"probes" with sharp points aimed aft, usually somewhere on the vertical or
horizontal stabilzers or both and occasionally on the ailerons.

<Idiot Mode>

I recently purchased a Radio Shack Pro 2006 Scanner. I've been
monitoring typical newby stuff like 800MHz trunked emergency
etc. I've just begun investigating satallite monitoring like
the ISS. My present antennae setup is a recently purchased
Radio Shack 20-043 discone located at ground level inside my house.

My questions are:
How much better will my reception be with the antenna in the attic?
How much better will my reception be with the antenne outside ~30' up?
I have about 40' of RG-58. Is this coax length overly excessive?
Does this antennae have to be grounded? Via a metal mast?
Are the typical Radio Shack solderless connections sufficient?
Should I disconnect the stock arial when using the 20-043?

Thanks for tolerating my ignorance.

</Idiot Mode>

Hi Joe,

Why don't you use a metal table or some old oil drum. Buy some paint and
some brushes and decorate it with nice flowers and butterflies. It works
well and I can tell you that from my own experience with other car
antenna's. You can also use some metal boards that they use for shelves.
Just take precautions against corrosion.

Good luck and happy painting.

Peter- I heard that it was because of insurance, among 'other things'- I dont really know. I checked the drawings in the Rohn book, and there is no mention of the bolts. They sell the folding assembly as a unit, according to the catalog.

The bolts on mine were in very good shape. It was first erected in the early 70's, and I got it about two years ago. In fact- all components except the winch were fine.

If you get in an absolute panic- I will go up and measure the bolts. just remember- it will have to be behind Iris's back (I'm 73). {that IS a real offer)

There are a couple of very helpful dealers on the 'TowerTalk' reflector, that can probably help you-- try there.

Hi OM&#65533;s
i looking for a method to calculate the L (how much uH) from form 1 loop.
(for a magnetic antenna)

I have one, but is this ok ??

L/nH =2*pi*{(2.3*log((8*D)/d)-2)*D}

Has anyone a other idea ???

Tnx a lot for help me.

Can anybody give me a rough idea of how well/bad these antennas perform. I am not looking for the best in DX, just something fairly discreet that will allow me to get on the local repeater while driving.

Also, my radio receives airband. Will it receive okay enough through one of these antennas ?

Thanks in advance,

Richard.

About the only thing that makes sense now is that you have shown yourself to be a moron. May I ask WHY in the heck you are attacking someone that posted a message siding with you and condemning others for their posts about you?

> Here you go blaming the victim again.

What? He SPECIFICALLY says, "Chip was
restraining himself, but some of them couldn't leave it alone." and, "it isn't always Chip's
fault!" Sounds more like you crying about being a victim again.

> Please stop this. Its only makes me look bad. I will never, ever, ever, accept

What the hell are you going on about here? He didn't portray you as anything. Yet again it is you that is making you look bad. Are you feeling a little guilty about something? It seems thou doth protest far, far too much.

> JUST BE QUIET! I should not be part--PERSONALLY-- of ANY conversations here.
> Any more than you, or your mother, or your son should.

I, my mother and my not yet conceived son have never declared ourselves to be experts in any NG. We have not made 2600 posts to this NG since dejanews last started recording. We have never given "public notice" of anything in this or any other forum. We have never threatened to sue half a dozen or more people in any NG. We have never made it painfully clear what our profession was in an attempt to give our opinion more weight in any NG. We don't have a persecution complex.

Hope this helps,
kb9wfk

stainless steel firearms are more prone to galling. Or used to be.
Supposedly the current stainless alloys are much better than they used
to be.

Ahhhhhh, well,

I still think at some point you will end up comparing the thru-glass antenna to something else and find yourself VERY disappointed. They work--after a <fashion>--but nothing to write home about. You will find receive to be several db less than a 5/8 wavelength and that even a 1/4 wave whip will beat it. It's, after all, your decision as to how much performance is "enough". Just remember; there are NO shortcuts in performance. You can have "Pretty". You can have "Performance". Almost never do they come in the same package.

What really happens in a lossless steady-state purely sinusoidal condition with no modulation? :-) Reg, we know reflections exist because we can see them as ghosts on a TV screen.

> There are several ways which this could be accomplished. Gears, or chains
> being the easiest.

That's sort of what I had concluded.-- that there is no off-the-shelf
equipment available to do it, so it would have to be custom. There
is also the matter of the thrust bearing(s) to take the weight of the
outer mast, and how to lock the rotor and boom(s) to the mast. Both
items seem to suggest welding plates onto the mast, since
throughbolts are not possible.

> As far as I know, no one is currently manufacturing systems like this, but
> there were similar systems a few years back.

I just got relicensed after a 20-year hiatus, and I am finding that
lots of things have changed. Lots of things haven't....

> BTW, extending more than a few feet above the tower top adds greatly to the
> wind load as well as adding a bending moment.

Few people consider that bending moment of a beam on a tall mast
until it's too late. Removing and lowering a hairpin-shaped mast and
the antenna(s) on it can be interesting.

Thanks, and good luck on the installation. Put pictures of it
somewehre for us to see....

Cecil just happens to be the latest on the list, according to my server,
so he gets to be the 'most recent reference'- ie, the one I answer.

Funny thing happened when I was looking for a reference to an Amp I saw-
I picked up the January 1995 issue of CQ, which is the 'Collectors
Edition' covering 50 years of Amateur Radio. Gues what the lead article was?

"Reflected Power Stays in the Coax", by Warren B. Bruene, W5OLY.
This article has several VERY well worked out diagrams, showing which
way the stuff goes, and where the waves are-

Very helpful- I need to study it, in detail, and compare with the LARGE
stack of print out from the recent "debate" (?)

Bill Aycock wrote:
> "Reflected Power Stays in the Coax", by Warren B. Bruene, W5OLY.

The scalar magnitude of reflected power is constant given a continuous wave signal but the reflected power does not stay in the coax. Hang a stub on a TV receiver and observe the ghosting which proves that the reflected energy is continuously being refreshed. Reflected power is dynamic and cannot be stored forever.

Well, I bid and won the thing. It was an impulse buy, the kid in a candy store syndrome attack. If all goes well, I'll get at least $9.99 worth of sh*ts 'n' giggles when I get it. If anyone has further info on this "ball" antenna, please let me know. For those who are curious, I'll post something here to let you know what it is, and how/why it works (or doesn't). At least now, I have something to leave to my heirs.

Well Wayne,

Here you go blaming the victim again.

Please stop this. Its only makes me look bad. I will never, ever, ever, accept a premise that I am the person portrayed here, for the simple reason that I am not that person.

I do not wish to convince you or anyone else of that: taking as an assumption that a person is worthless, evil, and so on, until proven otherwise is so foreign from the value system I grew up with that I cannot, and will not, entertain it.

JUST BE QUIET! I should not be part--PERSONALLY-- of ANY conversations here. Any more than you, or your mother, or your son should.

KEEP PERSONAl ATTACKS OFF this ng. Doesn't that make sense?

With best Wishes,

Chip N1IR

Richard:

I have seen you and others make this claim about stainless. I have dozens and dozens of stainless fasteners and other parts in various antenna and support locations and have never experienced this problem, unless they were seriously abused. About 30 years ago when I first started using stainless, I quickly discovered the need for Loctite or self-locking nuts, but have never had a problem with stainless deforming . Of course, I stay within load limits, which are lower than grade 5 steel, but that goes (I hope) without saying. What alloy stainless have you had this problem with, and under what conditions? My friend Torque (who shall otherwise remain anonymous, since he climbs for me) twists off small mild steel bolts regularly and grade 5 occasionally, so I wouldn't trust him with stainless and a wrench anyway.

On the other hand, I have to grease the galvanized turnbuckles every 3 months or replace them every two years, either of which is a pain.

Source record: 176050

Ready made insulators are going to be expensive. However, if you are willing to scrounge around salvage/surplus yards, you will find insulators you can adapt to your project for a few dollars. You can also go to plastics suppliers and check out their stock. You will probably find materials you can use.

I recently picked up (with great difficulty because of its weight) a piece of fiberglas epoxy measuring 4 feet by 4 feet by 2 inches. It weights over 100 pounds and cutting it will be a challenge, but it will make great insulators. It was at a salvage yard and was considered to be of no value because it could not be recycled easily. I got it in trade for some metal scrap I wanted to get rid of anyway.

Use your imagination and a little research and you will probably come up with something inexpensive that will work fine.

Good luck,

Roger K6XQ

Cecil, W6RCA wrote:
"The generated energy and the reflected energy indeed do see different conditions---"

For example:
1/4-wave line section (50 ohms =Zo).
Load = 25 ohms.
The line input will be = 100 ohms.
This is standard impedance inversion.

None of the reflected energy is returned to the source because the source has higher voltage at every point in the cycle when the volts are not zero.

We assume our source has an impedance of 100 ohms and is matched to the load we provide with our 1/4-wave matching section.

The source`s energy is not reflected at its terminals because the transformed load`s 100 ohms matches its input impedance.

It seems to me that the incident wave is delayed as it travels to the load by 90 degrees. At the load the voltage experiences another 180 degree phase shift, but no phase shift occurs on reflection in the current through the low load impedance. The reflected wave is delayed by another 90 degrees as it travels back to the source.

The returning voltage has gone through 360 degrees and has been reduced by the energy absorbed in the load. The reflected voltage fraction is: (Rload - Zo) / (Rload + Zo).
The line is lossless.

At the source`s terminals, as Cecil implied, there is a different condition from that at the load. It`s not just the impedance that`s different. There is also an energy source at the source.

We have a source voltage on one side of an internal impedance and a smaller reflected in-phase voltage at the output terminals. The current which flows out the internal impedance is motivated by the difference between the in-phase voltages on opposite sides of the internal resistance of the source. This causes us to see 100 ohms as a load, and not the Zo of the cable.

The Loctite is probably why you've had no trouble. The technical term is "galling", which is when a very irregularity on one thread plows into the facing part, and rolls up material from both sides like a snowball which binds the thread. Stainless steel is apparently very prone to this.

As well as locking and sealing the threads, the Loctite acts as a lubricant which prevents galling when the threads are being tightened. With galvanized hardware, the zinc coating does the same because it's much softer than the steel underneath.

As someone else said recently, the best place for tower information is the TowerTalk reflector. (It's where I got that information about galling and Loctite, from someone who installs SS hardware on ocean racing yachts.)

Yep, thats right. I don't know how I got disturbers in my head. Been
quite a while. And yep, I think he mentioned the same thing. If a few
missing, you couldn't fly. They had both types of wings also. The newest
one they had the newer wing with no tabs. They had two or three of them
in the hangar when I was there. All were fairly old. The newest one I
think a 35a. Maybe older than that , I forgot...

Maybe less effect than the radios. But just guessing. I would think the
higher the freq of the device the less noise problems. ADF being real
low freq would get whacked bad. I don't think I would like to fly in
storms too much. I even try to avoid them flying commercial jets. I had
to take a 737 to Little Rock about a week ago . I waited until all the
t-storms cleared out before I would get on that thing. We had a big line
of them the night before that. Luckily, I timed my reservation just
right, and left Houston with clear wx. Hit rain up north, but no big
deal. Just light stuff. MK

Hummm, I was thinking of something. I could use your expertise on
something if you fly lear's. I've been working on a panel for FS2000
flight sim, for the Lear 31a. I hacked up a few pictures I managed to
get, and am wondering with all the patching if I got the perspective
right, or even close. There is still alot of work to do on the gauges,
so not all are correct. IE: engine gauges need the faces painted, etc,
etc. Still quite a ways to go. I'll post a pix of what I have so far.
It's a jpg with reduced quality to speed the d/l. Only about 78k. Does
the overall perspective look about right, or do I need to zoom in
farther? Also does the cowling look right. I had to hand draw the top of
the cowling to the left, so may not look quite right. Howz it look
overall? Ok, or do I need to start over? BTW, Sorry for this non antenna
subject, but I tried to snare a few lear pilots advice on the sim sites
with no replies. Not enough real pilots around for the lears I guess. MK

Was detailed enough that I wanted to put in a little left rudder trim. One could quibble about the location of some of the secondary instruments. But these are left up to the owner, so no problem I see. The perspective looks OK to me.

Otto,

It's no use to measure the antenna height. Current(ampere) * meter says something about the magnetic field. Volt * meter says something about the electrical fieldstrength. The meters are measured as a distance from the point of radiation. The current is measured as the electrical current (ampere) within the RF energy at a certain distance (meters) from the point of radiation.

This is my humble meaning. Anybody have an other idea about this matter? Please let me know if you won the prize.

Good luck,
Adam

All a wave component sees are the components of the tuner. What you see when you perform a measurement is the sum of the generated and the reflected components. Are you saying an incident wave component behaves differently based on the conditions at the incidence point?

> A transformer treats reflected energy differently from generated
energy.
> It steps one up and the other down. Why can't an antenna tuner treat
> the two signals differently?

How does the tuner or the transformer "know" that a wave incident on it is either coming from the generator or coming from the load? How does it "know" to completely pass one and completely block the other?

BTW, the transformer is a reciprocal device. If Z12 = V1/I2 and Z21 = V2/I1, then for a step-up/step-down, Z12 = Z21, which makes it reciprocal.

Rick, dig out the articles in QST back in the 70's by Jerry Sevick,
W2FMI. He wrote up a 7 or 8 foot loadaed vertical he used on 40 with
ourstanding performance.

Short verticals CAN be efficient and useful provided that they are "done
right!" But, I take your point re the multi-band aspect. Jerry worked
only with monoband antennas.

> beams on the inner (taller) mast, would be nice,

That's the way I'm setting it up.

The innermost mast (1 1/2" steel pipe) sets into a conventional
rotor...Hy-gain 300.

The outer mast is driven via a heavy duty chain drive with the rotor mounted
external to the tower, or it will when I get that far.

There are several ways which this could be accomplished. Gears, or chains
being the easiest.

With gears, the thing to remember is to either use a third gear so the mast
turns the same direction as the rotor,*or*, reverse the direction unit
readout. (lots easier)

The outer mast (2" ID steel pipe) extends on up to the bottom VHF antenna
so it adds lots of support.

The machine work involves making the adapters for either the sprockets, or
gears. It also takes a bit of metal fabrication and a little welding to make
the offset rotor mount.

Right now the only thing on the tower is a quadature array of TV antennas,
which kinda, sorta work. They work better than a single antenna, but they
are extremely sharp and have three very strong side lobes (indicating to me)
that the spacing is not wide enough.

As far as I know, no one is currently manufacturing systems like this, but
there were similar systems a few years back.

BTW, extending more than a few feet above the tower top adds greatly to the
wind load as well as adding a bending moment.

In the last few days I've made a number of posts to RRAA. A number of them have disappeared.

I read one a few minutes ago (posted earlier today). Then went back to check some comments. I came up with the message that the post is no longer on the server. This has happened with over 4 posts today.

Any ideas?
Didn't think I'd pissed any one off, but those posts are going somewhere.

I haven't been able to find it in my copy, but it certainly makes sense as
that is the area where moisture can penetrate. The expansion and
contraction of the metal differes from that of the concrete and the
moisture as well as the air can penetrate about that far.

Roger (K8RI)

I'd not expect rust/corrosion any lower than that.

Static wicks (they don't normally have sharp points) are just stranded wire
pieces about 4 inches long that trail from the airlerons and elevator. They
are sometimes attached to the rudder and vertical stabilizer as well.

>
> Actually, thinking about it, if the ones you describe point aft, they
> are probably different from the disturbers. The vortex disturbers point

The vortex "generators", generally fit along the most curved portion on the
top surface of the wing. These actually keep the air attached to the top of
the wing at speeds below where the air will normally stay attached. This
gives reduced stall speed which may allow for increased gross weight.

BTW, even with static wicks, it's not uncommon to have to turn off every thing to get rid of the noise. Particularly on the nav radios. The ADF is the most susceptible and the VORs right behind it. I had to restart all the electronics twice within 20 minutes on one trip

I've not experience any problems with GPS yet, but I've not gotten into any storms of the magnitude that shut down every radio in the plane prior to installing GPS so I can't speak about its effects on GPS.

Hi and thanks for reading this post

I recently acquired a General Electric 40ch CB radio Model A3-5825B (twin board model) with the view of putting it on 10m.

Has anyone got the schematic diagram for this radio as I don't have one and the rig has been tampered with by someone. Currently the lights come on but there is no-one at home (no RX/TX). It appears that components have been added and subtracted but I don't know what the correct ones should be.

Any help would be appreciated. Scanned schematics are OK but please email me direct and don't forget to remove the SPAMJAM

Thanks in advance

How about a VHF/UHF vertical (say, 2.5 metres long) and a Butternut
HF6V (7.9 metres)? How close can these be on a tin rooftop (on separate
short masts) without interfering with each other?

Ok, Thanks for the look. Yep, many of the gauges still need alot of work. The autopilot is wrong and is just pasted in from another panel for now to be able to fly. The AOA is giving me a problem , as the only properly working one I have is the round kind you see on a few models. I want to proper rectagular one but will need to program a new gauge. The round one just doesn't look right in the 31a. To me anyway..The secondary A/S, altimeter,AI gauges are in the exact place as the picture the panel is made from, but I have a slight cutoff up near the top. Need to redo that I think. You can see the placard is cut off. A problem was the detailed pix didn't extend up into the A/P and cowling etc. So had to butcher in those areas from other pictures. The panel picture was taken from a corporate 31a and was pretty sharp in the original true color pix, but lost a bit in all the chopping and reduction to 256 color. I may make a 24 bit version, but will take a bit more memory to run and puts a bigger overhead on the video. Anyway still a ways to go...I don't know if you mess with the sims, but if you want a copy of it, let me know. I also have made a pretty detailed kingair 350, and a couple of panels for C-130. One a glass version, and one the old analog gauges. I have a few pix of the kingair panel on my server. It's fairly complete. Thanks again, I don't want to spend half a zillion hours working on something if it doesn't look right. Also open to any suggestions on it. :(MK

My 2 cents on Butternut. Excellent antenna and great service from the manufacturer. Based, on what I read, I won't be buying any Cushcraft products. No support and no parts? Sounds like they did not learn from the Japanese very well.

Regards,

Duffy - WB8NUT

Bill Aycock wrote:
"Reflected Power Stays in the Coax", by Warren B. Bruene, W5OLY."

Warren is about as infallible as I am. Reflected power loses the same percentage to the load on each successive pass as on the first. So most of the power is radiated. It simply can`t stay in the coax because there is no place for it there.

EMF does no work until current flows. When current flows, volts times amps is power in watts. Watts measures the rate of doing work.

In a transmission line, power is delivered to a load. The load for a radio transmitter is its antenna`s radiation resistance.

Work is done by the energy supplied which is power times time.

One measure of energy is the watt second. Most coax accepts input at a speed of about 120,000 miles per second, so a piece of coax about 120,000 miles long is needed to contain one second of energy at however many watts are being supplied. The energy is multiplied by the number of watts. Shorter lines contain proportionately less energy. But, the coax can hold energy traveling in the reverse direction, in addition to energy traveling in the forward direction. Total energy contained in the line is the sum of forward and reverse energies.

So, where does the power go? It enters the coax and travels to the load and is radiated except for some reflected power which circulates before being radiated. Losses in the system take a small percentage toll on each trip through the coax.

Richard Harrison, KB5WZI

Hello,

Man, I would like to reply to everybody with this response.
After a bunch of reading here and the "Reflections" series, I
feel a little bit better. Still, lots of uncertainty. After reading
through the reflection series and consulting the ARRL Antenna book,
I couldn't find "conjugate match" in the index of the book. I don't
understand how those articles can talk about it like its so common,
but I can't find it in the index.

First off, It obvious its hard to explain things when there are so
many variables. So, people must be clear about what the exact context
is when they're explaining things. And before you jump on somebody,
ask them to clarify.

Now, from what I understand....

Taking the solid-state rig, into 50 Ohm coax into a simple dipole
(no common mode currents ;) and no tuner example. The transmitter
transmits (on 80 meters), the signal goes out to the antenna. Part
is reflected back towards the transmitter.

Now, since there isn't a Z0 Match, does this mean *some* of the
reflected
power is absorbed by the final PA and some is re-reflected back towards
the load?

Its my understanding if there is a Z0 Match, the reflected wave sees the
reciprocal mismatch and is *completely* reflected back towards the
load.

First uncertainty, incident wave makes it back to the load...isn't
part of the signal old, and possibly out of phase (the wavelength of
the line) with the originally (already) transmitted signal? Wouldn't
this cause an echo or some cancellation/re-enforcement of the signal
overall?

The "Reflection" series seems to stress that if there is a Z0 match and
line loss is low, power eventually gets radiated so there isn't a
good reason to get SWR super low (from what I understood), especially if
the SWR is normally not supposed to be 1.1 (ground mounted 1/4 wave
vertical).

Next question, "conjugate match"..is this the same as "Z0" match?
What are some ways to "conjugate match"? (1/4 wave transformers?)

Next scenario, what if we take the above scenario and add a solid-state
amplifier in-line...still no tuner. Should there be a "Z0 match"
between
the radio and amp under all circumstances, or does a mismatch at the
load
in turn effect the Z0 match between the radio and amp?

I won't get email sent to the deja.com email address.

Thanks,

Scott McClements

There's a little history involved there. Go back and read an ARRL Antenna Book from the mid-1980s and you will find 'conjugate match' mentioned quite often. A few years ago, the ARRL purged 'conjugate match' from their publications allegedly because they believe a conjugate match rarely exists in reality.

> Now, since there isn't a Z0 Match, does this mean *some* of the reflected
> power is absorbed by the final PA and some is re-reflected back towards
> the load?

That's probably what happens. Depending on the phase of the reflections, over-current or over-voltage may result. In any case, the final PA is not seeing its designed-for impedance. It's possible for the reflected energy to make it all the way back to the DC power supply or battery.

However, conventional "wisdom" will tell you that reflected power absorbed by the transmitter wasn't ever generated in the first place.

> Its my understanding if there is a Z0 Match, the reflected wave sees the
> reciprocal mismatch and is *completely* reflected back towards the
> load.

Reflected waves are technically not re-reflected at a Z0-match. What actually happens is two complimentary sets of reflections perfectly cancel each other through an interference pattern. The "re-reflection" is a *scalar* process involving the conservation of energy. The canceled reflected energy simply has no other place to go except back towards the antenna (assuming a Z0-match).

> First uncertainty, incident wave makes it back to the load...isn't

At a perfect Z0-match, everything is perfectly in phase or perfectly 180 degrees out of phase. And yes, an echo (ghosting) can and does occur where modulation is involved.

> The "Reflection" series seems to stress that if there is a Z0 match and
> line loss is low, power eventually gets radiated so there isn't a
> good reason to get SWR super low (from what I understood), especially if

The reason for getting the SWR low is feedline loss. Ordinary coax is
much more lossy than open-wire line.

> Next question, "conjugate match"..is this the same as "Z0" match?

Nope, each is possible without the other. IMO, a Z0-match is all the
average ham needs to worry about since he rarely knows the internal
impedance of his transmitter.

Scott- very good set of questions- Cecil- excellent set of answers.
These help, especially put in a one-to-one context, as you did.

Comment about the indexing system used in ARRL publications- "they do
not understand the concept"- for example- try to find the word "Coax" as
an entry in any ARRL handbook before about four years ago- and "Coax" is
MUCH more commonly used than "Conjugate match".

Bill

2845. Reflected power test

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-21 00:00:00 UTC
From: Fred Hambrecht <Fred@w4jle.com>
Message-ID: <8ve5dg$2ku$1@iac5.navix.net>
Source record: 175954

OK, I want to run a test to see if the reflected power gets out or not. Here is my plan, please comment as to the validity of my testing methods.

1. A gamma matched dipole (2 meters) is adjusted for a 50 Ohm match. It is fed with a length of coax that is an electrical multiple of 1/2 lambda. Field strength readings are taken in the near and far field.

2. The Gamma is adjusted to obtain either a 25 or 100 Ohm match. A tuner is inserted, tuned for 1:1, between the transmitter and the feedline and a second set of readings taken.

3. The tuner is moved to the antenna end
again tuned for 1:1 at the antenna end. Readings are taken.

4. I suspect that none of the above mentioned tests will produce any difference in the field strength.

5. If that is the case, is the argument the total power of a given time will be less because of the reflections stored in the coax? If so, how can I measure it? I know how to mathematically analyze voltage and currents at any point on a line caused by reflections. However if I cannot see a difference in field strength are we, for practical purposes, jousting at windmills?

Rohn makes some really heavy duty thrust bearings which I'm using to support both the inner and outer masts. They feel a bit rough when unloaded, but with load from the masts they are as smooth as silk.

The outer mast is supported at the top of the tower and again about 11 feet down for alignment. The inner mast is supported about 3 feet below the bottom of the outer mast and again at the rotor (alignment only). The bottom rotor does not support any weight.

I have a ways to go to get this finished and probably won't be driving the masts seperately until some time later this winter, or even next spring.

As for connecting the adapters to the masts, the easierst way I've found, is to use a "keyed" setscrew arrangement.

My adapters are long enough that I can use either a 3 or 4 screw arrangement on top and bottome of the adapter.. The mast is drilled just deep enough to allow the end of the set screw to fit into it This makes for an arragement where none of the screws have to be super tight. That makes 8 of them Just good and snug.

It takes two things: Good insurrance and a hacksaw<:-))

There are two pictures of the old installation and one of the partially
completed new at http://www.rogerhalstead.com/kim.htm There are a couple of
the old Debonair on that page as well.

They are pretty high resolution so if you don't have a fast connection ....
It takes a while.

I hope to have a history up on a page "tower.htm" shortly. Those will be
thumbnails linked to high resolution JPGs which will make the page much
faster to load.

If you have local ground wave noise from one direction you can reduce it with a small loop by nulling the noise.

If you have skywave noise, a small loop will make no difference at all in ratio of signal-to-noise.

If you have noise generated very near the antenna, a small loop may be either better or worse than any other antenna.

Often the improvements with small loops are caused by the reduced signal level, whick prevents sharp noise pulses from"squaring off" in the receiver and being lengthened. An attenuator pad will often accomplish the same thing.

I'll be interested to see what you find and, here's some thoughts.

>1. A gamma matched dipole (2 meters) is adjusted for a 50 Ohm match. It is
>fed with a length of coax that is an electrical multiple of 1/2 lambda.
>Field strength readings are taken in the near and far field.

<snip>

>3. The tuner is moved to the antenna end
>again tuned for 1:1 at the antenna end. Readings are taken.

Will the gamma be left at the 50 ohm setting, or changed to something else and, if so, what's the difference electrically?

In my opinion, the gamma is a form of antenna matching system anyway. Just like the 'tuner' that you propose to use at the other end. Except that the 'tuner', when used at the rig end, is an 'antenna system tuner unit' acting on the impedance presented at the rig end.

One likely difference in the reading that you will take are the losses in the tuner unit..... I presume that you will be giving some thought to measuring the losses in the tuner unit before you begin? Will the tuner unit will be in circuit when the dipole is matched to the feeder by the gamma match?

Also, how accurate is your field strength measuring device? Will it be permanently mounted in place during the tests, and will it be kept at a constant temperature as well?

How accurately will the transmitter power be kept at the same level during the test? How accurately will you measure the power output? Even if the field strength measurement is 'relative', the effect of variations in output power of the transmitter may make a difference.

Just some 'off the cuff' thoughts. Others may disagree (probably violently. HI!)

Dino,

That "article" was nothing but pure marketing bullcrap. It was designed to plug a product, and in the process gave some very very poor advice and theories on antennas.

Someone was dreaming.

1.) If the bulbs themselves were radiating the RF, it would be virtually impossible to phase them.

2.) The ionosphere does not have non-linear properties at normal power densities. That was all BS.

3.) Virtually all tribanders do not have less gain than dipoles, or the same gain as verticals.

Someone must have had a "buddy" at QST to have gotten that nonsense printed.

Fred,

Will be interested in your results.

This may have appeared here, but there is an old test which may be of interest. The late Lew McCoy talked about it in an article. Sorry I don't have an exact reference, or the details of the tubes involved. Too many years ago.

After WW 2 coax became very cheap and popular. People started getting worried about SWR losses, which was never a concern, rightly or wrongly, with ladder lead. Someone (Lew?) built up a very simple HF transmitter which used a tube in which the red glow of the plate was very apparent at high levels of plate dissipation. Small changes were readily visible. He used 75 ohm cable, and 2 non-inductive 150 ohm resistors. They could be seriesed or paralleled to give 300 or 75 ohms for the load. The matching network was designed to cover this range.

First the rig was set up with the load as 75 ohms. The power was adjusted so that the plate glow was very apparent, and changes in dissipation were easily visible. Plate current and voltage were noted. I think they also looked at rf voltage across the load.

Next, the load was changed to 300 ohms, or a 4:1 SWR. The rig was retuned, and the plate current and voltage reset as before. The plate glow was exactly as before. Certainly nothing like the reflected power we talk about was being dilapidated in the plate. Again, I believe they checked the rf across the load as well.

Conclusion: with correct matching, which of course modern rigs lack without external help, the only loss will be in the coax due to the large currents. Or in other words, a lossless coax would deliver all the power to the load no matter what the SWR, as long as proper, and lossles, matching is used.

By and large, yes, unless you are running at the power specified by
the manufacturer where the output Z is specified (50 Ohms). If you
have any doubt as of this specification, simple refer to the
characteristics listed in your tech manual for your rig.

Even here, there can be some variation from 50 Ohms. My own rigs are
specified as 50 Ohms, but under less than full power they exhibit Z's
that are not 50 Ohms and yet do not fall below 35 Ohms nor rise above
70 Ohms.

You probably can assume fairly similar characteristics given that
finals design for transistor rigs has not changed much in the last 20
years.

Yes, but do not dwell on this greatly as SWR does not contain phase
information and trying to pursue this thought without all the
information will only frustrate.

Hi All,

During my tenure in Metrology, the standard text on the subjects
Conjugate Match and Z0 Match were formalized. Insofar as your access
to the NBS standard methods, these definitions may be found in
"Microwave Theory and Applications," Stephen F. Adam; or they
may be found in Hewlett-Packard's Application Note 56, or they may be
found in the original works by R. W. Beatty published in IEEE
Transactions in the early 60's.

The following terms are those understood by Metrologists at NBS and Primary/Secondary Standards Labs:

Substitution Loss:
A general term referring to the change in power absorbed by a load when first one waveguide junction (these words are used in the broadest sense) and then another (such as an attenuator) is used to connect a source to the load.

Transducer Loss:
What the substitution loss becomes when the first waveguide junction is a perfect transducer and initially the maximum available power is delivered to the load.

Insertion Loss:
What the substitution loss becomes when the first waveguide junction is a perfect (lossless and phase-shift-less) connector, so that in general there is some initial mismatch loss.

Attenuation:
What any of the above losses become when the source and load both have Z0 impedance. Under these conditions, what is measured on an attenuator is a property of the attenuator alone, so that this is the ideal system in which to make measurements.

Residual Attenuation:
The minimum attenuations of a variable attenuator. What is measured when a variable attenuator is set to it minimum position and inserted into an ideal system.

Incremental Attenuation:
The change in attenuation between minimum setting and any other setting on a variable attenuator. Residual Attenuation and Incremental Attenuation together make up Attenuation.

Conjugate Match:
The condition for maximum power absorption by a load, in which the impedance seen looking toward the load at a point in a transmission line is the complex conjugate of that seen looking toward the source.

Conjugate Mismatch:
The condition in the situation above in which the load impedance is not the conjugate of the source impedance.

Conjugate Mismatch Loss:
The loss resulting from conjugate mismatch.

Z0 Match:
The condition in which the impedance seen looking into a transmission line is equal to the characteristic impedance of the line.

Z0 Mismatch:
The condition in which the impedance seen looking into a transmission line is not equal to the transmission line characteristic impedance Z0. In general, conjugate match is a case of Z0 mismatch.

Z0 Mismatch Loss:
The loss resulting from a Z0 mismatch.

Conjugate Available Power:
Maximum available power.

Z0 Available Power:
The power a source will deliver to a Z0 load.

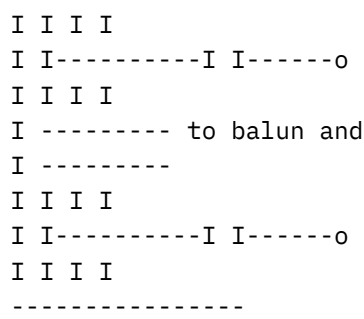
Hi Tom,

if the local noise is produced closed to the antenna, a loop should help.
A loop mainly reacts to the magnetic field component of the EM wave. If
your noise source is so far away that you 'see' only its far field (more
than maybe a wavelength or so), than this makes no difference. If you have
a noise source close to the antenna so that you are in its near field than
a loop should help a little because the magnetic near field goes like
1/distance^3 whereas the electric near field goes like 1/distance^2, so
that you see mainly the electric near field.
I think it is this why people say you have less noise on a loop. Propably
you will also have less statics produced by corona discharge on a loop.
High selectivity will perhaps help against front end overload from a
nearby broadcast station.

I think using 4 to 5 windings in a 1 by 1 meter square resoanted with
a 500 pf capacitor should be a good starting point. There are formulas for

the inductivity in the ARRL antenna book, I have an older edition (14 or 15), but as far as I know they didn't take them out. For coupling to the receiver there are many ways, when I was playing with a 40 to 80 meter rx loop I used 1 turn 2 by 2 squared, a 250 pF capacitor connected to the ends of the wire, a low value ceramic capacitor connected to each of the joints and a balun. The ceramics were around 20 pF (less than I calculated before).



Other people use a additional single turn loop for magnetic coupling, most transmitting loop are such that the area of the main loop and the coupling loop are related at about 50:1, maybe one should try to realize the coupling such that this will hold for the product of # of windings times side length^2, but the ratio depends on the Q of the loop anyway and is not too critical in receiving. Best is perhaps a high impedance (does it need to be balanced ?) FET amplifier to match to your receiver but didn't try this.

Hope could give you a starting point.

2854. Re: Through-the-glass 2M antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-21 00:00:00 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3A1AC191.4740F019@bellatlantic.net>
Source record: 175963

You will be VERY pleased - if the antenna does what you want.
I built one, and was able to work all the repeaters I wanted to.
Happy as a pig in slop. A clean, neat, "stealth" installation -
the antenna looked like a cell phone setup. BUT when I needed
to work through a new repeater a few years later, I went for a 5/8
on the roof, which gave me better performance for the greater
distance - and more importantly, worse topography - I had to cover.

A thru-glass antenna is simply an LC circuit. Tuned properly, the
RF path through the glass is essentially lossless. The performance
difference between that antenna and say a 5/8 has two main
factors: The difference in freespace radiation patterns of a 5/6 wave
vs a 1/2 wave is one, and the impact of positioning on the vehicle is
the other. And the positioning affects the pattern in the "non-freespace"
installation. Now that may be interesting for discussion - but it has
nothing to do with whether or not you are pleased with the antenna.
If the thing does everything you want it to do, who cares if a different
antenna can do more? So you have to try it to decide.

Hi !
I want to calculate the L component of a Magnetic loop.
Is this right ???

r=radius
w=width of the loop lipe

L=12.57*r*log(2*r/w)+0.08

(Magnetic) Loop
N=1, r=50cm , w=1 cm
L= 2.8944 uH

(Magnetic) Loop
N=1, r=50cm , w=4 cm
L= 2.031 uH ?!?!?!!!??!

Can is be when the w increases then L component decreases ?!?!?

Tnx for help
Wolfgang

The easiest way to prove that reflected energy gets radiated seems to be using a modulated TV signal. You don't even have to run the actual experiment as a mental experiment will suffice. The actual physical experiment is like setting up a photocell to prove that the sun comes up.

Set up an amateur TV system with reflections on the feedline. Ghosts will appear on the TV receiver. The multiple ghosts will be equally spaced and decreasing in magnitude. One could even make it a closed cable system so that actual RF radiation is not required. One can estimate the length of the feedline and the SWR at the transmitter by looking at the received TV signal.

Let's say the characteristic impedance of a lossless feedline is 51.5 ohms and the load is 300 ohms. Let's assume a Z0-match at the transmitter end. Half the power incident to the load will be reflected. 50% of the power incident to the load is the most recently generated power. The other 50% of the power incident to the load is an infinite series of reflected powers of the form: 1/2RP1 + 1/4RP2 + 1/8RP3 + 1/16RP4 + ...

So the total radiated power would be 1/2GP + 1/4RP1 + 1/8RP2 + ...
where GP is generated power and RP is reflected power.

I stay well away from thunderstorms, but heavy rain will at times create
lost of statice, but nothing like snow. Really cold "dry" snow creates an
unbelieveable amount of static.

Last Summer I flew the approach into 3BS. We were at 7,000 and had to start
down about 40 miles out. As soon as we entered the clouds (just under
7,000) we were in torrential rain. It was a nice smooth ride and no static
at all. We broke out about 3 miles from the airport. About a mile to
either side of us the ceiling dropped well below minimums. It was like
flying in an inverted canyon.

I had an ungrounded 1/4 wave 40 meter vertical.
We had a strong wind and heavy snow. The end of the RG-8 was disconected
and there was a bright, fat, blue arc that was coming out nearly an inch
before coming back to the shield. It was creating a pop like a small
firecracker. "Quite loud". It would "pop" about every 10 seconds.

I've never seen an ignition system, including the mags on the plane, put out that hot a spark.

Having gotten nailed on many an ignition system, I left that litter sucker lay their until the storm was over. After that I grounded both the shield and center conductor.

I forgot to point out that the power magnitude of the above infinite
series is the same as the power magnitude of the generated power so
there will be no difference in steady-state average signal strength
with and without reflections.

>that you see mainly the electric near field.=20

At a distance greater than about 1/10th of a wavelength from a small
closed loop, the field response is mainly electrical....not magnetic.

The field response of a small vertical is mainly magnetic at the same
distance.

Very close to the antenna, that changes and the loop mainly responds
to magnetic components.

At any distance, it is pure blind luck if the loop is quieter than any
other antenna due to near-field coupling.

>I think it is this why people say you have less noise on a loop. Propably
>you will also have less statics produced by corona discharge on a loop.
>High selectivity will perhaps help against front end overload from a
>nearby broadcast station.

If the weather is so bad the antenna near earth has corona, you have
no business on 160 meters. The static from the surrounding area will
be so bad the corona will be meaningless. The exception might be if
the loop is on the top of a tall tower or building.

My verticals are just as quiet as any loop would be, because there is
no noise source within 50-100 feet of the antennas. If there was a
noise source close by, it would be pure random luck if a loop produced
better S/N, because it would depend on the field impedance of the
near-field of the noise source. Most noise sources are likely a
modest field impedance, since the conductors that radiate the noise
are often long and connected to many low impedance paths to ground.

So it is a matter of luck. At my QTH, I use only arrays of verticals
and Beverages for receiving...and the verticals are generally best.

I can't imagine *anyone* believing that. The powre is going to get out
of that coax one way or the other, if it's by only heat loss resulting
from the natural losses present. If it's to high a level for that, it'll
excape as light-when the coax burns. If the coax is lossless, it has no
REASON to stay within. Nuts.

2866. Re: Calculating Magnetic Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-21 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8velpc$36a$1@uranium.btinternet.com>
Source record: 175975
Cross-posted to: de.alt.radio-scanner,rec.radio.amateur.antenna

The important thing to calculate is the capacitance which resonates the loop to the wanted frequency. Which is NOT the capacitance which resonates the DC or LF loop inductance to the wanted frequency.

This is because the loop is a transmission line having a length which is an appreciable fraction of a wavelength. For example, when the loop perimeter is nearly 1/2-wavelength at the required frequency, the tuning capacitance is zero pF.

But if you use the ordinary formula for calculating the capacitance necessary to tune the loop inductance to resonance, obviously you will obtain the wrong answer when the loop is already a half-wave resonant length all the way round.

For a sufficiently exact analysis of any regular-shaped magloop antenna download program MAGLOOP4 from my website. For a slightly less but sufficiently accurate analysis of rectangular loops download RJELOOP2.

I havn't checked your formula but it is probably the DC loop inductance.

Yes, when the diameter of the loop conductor increases, the inductance of a loop of the same circumference decreases.

By my understanding....
When you have the Tuner at the Antenna end, you get better efficiency.
I think that it could be understood & measured better at a higher SWR.
2:1 is just a drop in the bucket...

Well, to be fair, we should say that during steady-state conditions
with continuous wave signals, the magnitude of the reflected power
in the coax is constant. Perhaps that is what Bruene meant. For instance,
200 watts stays in the coax until the transmitter is shut off. It's not
the same energy but is the same *amount* of power.

Cushcraft withdrew the R-7000 from production after about a year. Do you get the hint?

It was pretty good when it was performing but couldn't handle power, had much narrower bandwidth than advertised and the traps fell apart. I know this from sad personal experience.

Cushcraft should have offered everyone their money back or at least a discount on a new antenna but they didn't.

Thanks to all that replied. I changed the wire for the antenna and double checked the jumper issue and it know receivers well. The jumper connection was not quite being made, that made a difference as did new wire and new connections. Now all I have to do is get more comfortable in tuning it up so that I can get a low SWR. Too many years being used to an automatic tuner on my TS440. To bad the auto-tuner on my TS440 will not accept ladder line.

Source record: 175984

Hello all,
I'm new to this group, so sorry if this posting is out of subject.
Does anyone know what is the 'resonant frequency' in a microstrip
antenna? I have heard a lot of things, like 'the frequency where Mag(S11)
becomes minimum', 'the frequency where 'Re(Zin) becomes maximum' and
'the frequency where Im(Zin) becomes zero'. None of these is the same with
each other, especially with coaxial cable feed.
Also, is there any specific design procedure to find the 50+j0 Ohms point
in a patch antenna?

Please reply at: danagn@avdira.cc.duth.gr

Thank you very much,
Dimitris

Source record: 175987

Group- I really thought SOME of you would read the article, rather than just the title. In the article, his point is that the reflected power stays in the coax on the way back toward the source, but when re-reflected, is the same as applied power, and is dissipated over a few cycles, in the load. the energy stored in these 'bounces' in the coax, is small at any time.
His illustrations are in terms of voltage and current, rather than power, and he makes the point that the re-reflection is caused by the input voltage, not the hardware. This causes the phase of the outward reflection to be controlled by the source.

I wish a person with more qualifications that I have would read the article, and comment.

Lest anyone misunderstand, a tuner does not change the SWR
between the tuner and the antenna. All your "low SWR" is
indicating is a match to the transmitter's designed-for
load.

Trust me, I know the difference between "vortex disturber" strips and static charge dumpers. Done some fly stuff myself. V-22 Osprey build #3 is parked abt 75ft. from the cube I've been occupying of late and the whole butt end of the thing is loaded with 3/8" diameter pointy rods aimed aft which toss charges back where they came from . The last thing Bell or Boeing could give a rat's patooie about is dressing a V-22 up with vortex disturbers. The damned squirrely abomination wouldn't get off the ground, which it certainly does, without the monstrous vortxes it's Allisons generate.

I had a ten meter 5/8 GP that would do that. But not quite so loud. But it would arc from center pin to shield about every ten seconds or so when I had charged clouds going over. No rain or anything. A grounded coil could have cured that, but I prefered ungrounded as I used that antenna on 30m also as a 1/4 wave. It's funny, I had the 32 ft 40m antenna at 36 ft which was longer and higher then the 10m ant and also ungrounded, but it never arced in any wx. Go figure...:/ MK

Dear All Friends,

Why don't yawl put some numbers in the classical transmission line formulae and discover, before its too late, what really happens.

Or, if you have no faith in formulae, just set up a signal generator + line + attenuator + load + voltmeter and discover the same things.

It's really very simple. Please don't drive yourselves into nut-houses by haggling and quibbling about imaginary quantities such as reflected watts and the time taken to transfer from A to B. I cannot promise to pay visits to your solitary confinement cells because of travelling expenses. But I wish you all well.

I have the Larson 2/70 Dual band thru the glass antenna installed on my Nissan Altima.
It works well however not as good as if it were solidly roof mounted. A Problem with the antenna which I don't care for is that excess coax calbe is used for matching which suggests that there may be RF on the outside of the shield. While this has not caused me any problems it is conceivable that some cars may hiccup if the RF gets into their computers. Also many cars used metallized winshield tinting which will adversely affect the antennas performance.
Out of band performance drops off significantly out of band. The 162.55 MHz weather station which is only six miles away on a mountain top comes in marginally with this antenna.

Good luck...Dick K7RNZ

Keep in mind that Sprint uses the PCS system which operates at 1.9GHz
and will not be compatible with the amplifiers illustrated in the link.
CDMA (Code Domain Multiple Access) as sell ast TDMA (Time Domain
Multipe Access) are spread spectrum modulation schemes and have nothing
to do with the frequencies used. I would suggest changing cell phone
service providers before adding amplifers and taking other costly and
possible illegal means to solve your problem.

Message-ID: <8vh2o1$45$1@neptunium.btinternet.com>
Source record: 175869
Cross-posted to: de.alt.radio-scanner,rec.radio.amateur.antenna

Loop inductance =

0.2 * P * (Ln(4 * P / d) - K) microhenrys.

where P = loop Perimeter or circumference.
d = conductor diameter.
Ln = logs to base e.

For Circle K = 2.451
For Octogon K = 2.561
For Hexagon K = 2.636
For Square K = 2.853

A circular loop is harder to make and fix than a square but
its performance is only about 1 dB better.

There may be a change in the magnitude of reflected power AND
forward power but the reflection coefficient and SWR stays the
same. The load impedance and Z0 dictate the SWR no matter what
the generated power level (except zero of course).

With a resonant 160m dipole, the shorter the ladder-line, the better. Every foot of feedline up to about 115ft takes you farther away from resonance. For instance, with 100 ft. of ladder-line, the impedance at the transmitter will be very high.

Will an 80 meter Ham stick antenna work (I know the couplers will match it) with an end-fed wire coupler such as SGC 230 or Icom AH-4 better than just a 102" stainless steel whip? I have tried both couplers with a Hustler coil antenna and both seem to match,
however, results from earlier posts were telling me that on the higher freqs the full antenna was not being used and the loading coil was acting like a trap? Theroretically, wouldn't an 80 meter Hamstick antenna act like 60-65 feet of wire (to the coupler and rig), although it is shortened, lossier and not as effective? How would it behave on the higher freqs? Wierd lobes?
What difference (besides cosmetices) would there be if I just took 60 feet of wire and wrapped it around a stiff fishing pole?
Should I just stick with a SS whip?
The SGC-303 whip works very well considering what it is, but it is very pricey and I don't want to buy another if I don't need to.

2902. Second Shield of Double-Shielded Coax

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-22 00:00:00 UTC
From: Al <ABurzynski@swri.edu>
Message-ID: <t1ob0kkn5eep67@corp.supernews.com>
Source record: 175878

Where/how do I connect the outer shield of double shielded coax if I use this coax as the feed line from my receiver to antenna? Should the two shields be shorted at both ends of the run or just at the receiver? I plan on using BNC connectors at both ends of the cable. My main reason for using double shielded is that it is supposed to reduce RFI pickup, and I'm fighting quite a bit of it.

I guess I'm going to break down and get the ARRL Antenna Book. $30 is quite a bite but I hope it will answer some of these questions.

Thanks for any info.

Date: 2000-11-22 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A1C2B13.4CDE8EA5@eznec.com>
Source record: 175879

I've used a slingshot for many years for Field Day and other portable operation, but not for a fixed home antenna. The problem is that the line very quickly digs into the tree and seizes, so it's impossible to get the antenna down after a few days. But I've only used nylon twine or rope, and with Douglas fir or other pitchy trees. One person some time back reported using very heavy nylon monofilament fishing line and was able to get the antenna back down -- apparently the line is slippery enough so it can be pulled even after cutting into the tree. I don't recall what kind of trees he was putting the antennas up in.

What's your experience with the kevlar rope? Can you get the antenna back down after a month or two? What kind of trees?

Roy Lewallen, W7EL

Yep, I guess you missed my 2nd post.. I came to the same conclusion being as they point backwards instead of straight up. Also I was calling them the wrong name anyway. Should be vortex generators. Yep, the v-22 a strange animal. I had a model of one of those I tried to rig up for the sim. It sorta worked ok, not the greatest though. It flew, and you could change the pitch of the rotors, but it still wasn't too accurate I don't think. Maybe could do a better one now the the air file technology has improved a bit. MK

I'd be surprised if you'll see any difference in RF pickup by using the double shielded cable. I've seen a noticeable difference, but only when looking at very small signals using extremely well shielded test equipment. You should connect both shields at both ends of the cable just as you would a single shield.

I doubt you'll find that information in the ARRL Antenna Book, but in my opinion it's a terrific bargain at $30.

Al,
You would need to connect the shields at both ends
of the coax run. And worse than that, I'm afraid that
really isn't going to do anything to help with your
RFI problem. I seriously doubt if your getting the
noise because of the coax shielding...

Rudolph,
The HamStick ought to work with your tuner very
well on 80 meters. It should work as well as a 102"
whip on the higher bands, and probably better, maybe.

============================

Cecil, I am referring to the reflection coefficient and
mismatch presented to the line by the internal impedance of
the transmitter as modified by the tuner. Obviously, for
energy reflected back from the antenna towards the
transmitter, this will result in standing waves on the
line - and the magnitude of such waves will depend on the
tuner setting.

I missed the origional message. If the antenna is used for receive only
and unless there is a transmitter nearby such as in a repeater I doubt
the double shielding will help. Most of the RFI will be from the
antenna unless a transmitter coax is close to the receiver coax.

The shield should be connected at both ends. What kind of coax is being
used ?
If BNC connectors are being used it sounds like rg-58 type. For the
rg-8 size I usually get the 9913 type where there is a foil shield. NOt
somuch for the sheilding but it usually has a lower loss and the price
is about the same as a good grade of rg-8 type.

Are you a ham now??
If not you'll need to pass the Technicians exam, a 5 word per minute Morse code exam, a General exam and finally the Extra exam. The ARRL does have a Web site with information on getting licensed and finding a test location near you http://www.arrl.net/hamradio.html

The W5YI group also has study materials http://www.w5yi.org/TheWorks.htm

Hello Pete:

Can't help with the manual. I have lost mine too. Please inform me if someone offers a scanned version, as I would like to see the information again.

You might like to see how I modified mine for operation on the FM broadcast band here in Canada. After a few years of great service on 2 metres, I frequency scaled it for 106.3 Mhz and it is now located at 450 feet above the centre of the city of Winnipeg.

Here is a link to the station's site. Go into the pictures section, and you'll see the V2R and the transmitter site.
http://www.ckvn.com

Enjoy the antenna...it has survived some very strong winds while carrying a great deal of ice and still is in fine mechanical condition after 4 years of service.

Regards,
Lee Smith

To get the Extra class license, you'll have to pass the Technician, General, and Extra class written tests, as well as a 5 word per minute code test. The ARRL Extra Class License Manual prepares you for the Extra written test, but makes the (reasonable) assumption that you already know the material for the other license classes.

I'd recommend the ARRL study manuals for the other license classes. They cover all of the material that's on the test, plus they have all of the questions in the exam pool. Even if you have a very strong background in electronics, you'll still need to know the FCC rules, amateur operating procedures, and other details.

I used Morse Academy to learn the code. It's available as freeware from several web sites, such as

http://www.ac6v.com/pagez.html

Finally, you may want to find a club in your area that offers classes. That's the route I took, and it was very helpful. Not only did I get my license, but I met some fine people who taught me things that aren't in the books. I have a degree in Physics, and some college level courses in electronics, and a long term interest in amateur radio, but I never got licensed until I finally decided to take a class and join a club.

Good luck,

Tim

2918. Suggestions for (indoor) small space HF antennas?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-22 00:00:00 UTC
From: Don Faulkner <dfaulkner@pobox.com>
Message-ID: <3a1c9874@inout.beachnet.com>
Source record: 175894

Hello, all.

I've recently moved to the big city (LA) from Arkansas, and I'm trying to get my HF station back on the air. My most immediate problem is finding a good antenna solution.

I live on the 2nd floor of a 3 floor building. As you can imagine, getting any antenna up is going to be a challenge. I do have a balcony that I could use, but the railing is wood, so I expect I'll have to find a good ground. Of course, I'll have to do that indoors as well.

I'm considering a 1/4-wave end-fed wire (for 40M) with a balancing 1/4-wave ground. My initial thought was to run the driven element in a loop around the ceiling of my spare bedroom, and treat the ground element similarly around the baseboard. With this setup, though, I'm concerned about the amount of RF exposure in the bedroom, let alone the rest of the unit. I know I'm going to have to keep the power down, and that of course limits my abilities.

I'm sure there are other folks in similar situations. Can anyone offer me some other options that are perhaps a little safer?

What about RFI and neighbors? Is there anything I can do to minimize the effects of my operating (primarily 40M, 10M, 6M, 2M, .70M)?

Hi Wolfgang,

I don't know from where the formula is, there are severeal around with slight modifications of the numerical constants.
I think the observed behaviour is normal. If you take the formula for long cylindrical coil (something like L proportional n^2 A^2/length), you see that keeping the number of windings constant and making the coil longer decreases the L.

As a very rough argument I would say that the observed decrease in your formula can be understood by saying theat the coil is longer. Maybe another reason is that the area inside the wire is slightly less ?

Hope somebody can show a more quantitativeexplanation since the presented arguments are very rough. Anyway all formulas I know show this behaviour

You may have to go into the TV menu and setup the tuner to "air". Or at least see what mode it's in. "norm/catv" etc. You want normal if you want to watch UHF from that TV tuner. This would apply to the VCR if the VCR is the tuner being used. Sounds like a TV setup problem rather than hardware. MK

2923. A New In-Line HF Return Loss (SWR) & Power Meter

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-22 00:00:00 UTC
From: Paul Kiciak <pkiciak@att.net>
Message-ID: <3A1BBD45.63302AF1@att.net>
Source record: 176006

I've just put a new website together that describes a design for a return loss and power meter. Using this meter, you can measure up to 30 dB of return loss, which is equivalent to a 1.07:1 SWR, with as little as 1 milliwatt of forward power or as much as 300 watts. And it will also display forward power from 10 milliwatts to 300 watts.

If you're interested, go to:

http://home.att.net/~n2pk/

All comments or questions, sent to this ID or n2pk@att.net, would be appreciated.

73,
Paul, N2PK

2924. Re: Tower Guying question (Stainless steel or galvanized?)

OK, I capitulate. I see what's going on here.

First question on the installation sheet:
Do you use a 16 lb. hammer or a 24" Crescent wrench to drive the bolts
through misaligned holes?

Second question:
How much do you deform the hardware before deciding it is tight enough?

I understand now. Thanks for making me consider the caliber of the average
users. Alignment tool??? What's an alignment tool???? Torque wrench????
Yeah, I like the loooong handle, it gives me lots of leverage. Don't know
why the little gauge bent and the needle popped off, though.

Correct response: If you have to ask, don't use stainless. Use grade 8
hardware and spray with cold galvanizing compound. Or not.

Hi Tom,

thanks for your reply.

You write that a loop mainly reacts to the electric field component at
some distance. Is there an easy explanation for this ?
I always thought that a small loop is reacting to the time derivative of
the magnetic flux passing through its area. Seems I'm wrong. I know there
is a thing called 'antenna effect' responsible for the coupling of the
loop to the electric field component.
The german equivalent to the FCC demanded that you measure both the
magentic and electric near field to ensure that you are withing the limits
of the allowed near field strenghs. There is a study saying that the limit

for the magnetic field strength is the main problem when you use magnetic transmission loops while in all other cases I know it's the electric field. It is mainly this observation that brought me to the idea that the reverse is also true and that the loop mainly responds to the magnetic field component. Is there any literature about the effect you mentioned ?

When I had up my RX loop for 80 and 40 metres, I could only compare it to a piece of wire in the attic (20 m long). The loop was in my bedroom close to the wall (I put nails into the wall to hold the wire). The loop was inefficient on 80 (low S meter readings) but I could copy 9M, JA, VK, ZL etc. with this antenna, while I didn't hear them on the wire and my impression was that noise from nearby TV sets was suppressed (although still loud). I think there is no good or bad antenna (only a better or worse one), it's just what you compare it to.

Is your beverage better than a single vertical ? I don't know what the directivity of your vertical array is and how long your beverages are, but if the directivity is comparable then your judgement is no surprise, at least if you ascribe the 'noise suppression' of the beverage to its directivity.

At some point reliance must be placed in a tower crew. You can insist on torque wrenches, but hardware which withstands abuse is a better solution.

I recall a batch of galvanized bolts from Venezuela that litterly lost their heads when the tower crew overtightened them. That didn`t happen with U.S. made bolts.

Different bolts worked better than torque wrenches in avoiding the popping bolt head problem. After 30 years, there is still one tower in Minnesota standing with torqued Venezuelan bolts holding it together. I wouldn`t want to do any more that way. We had to witness every bolt assembly to ensure the torquing was proper.

Jerry,
I'm sure you know that any/all manufacturers build-in a
safety factor. By exceeding those specifications, you are
'eating away' at that safety factor. That decision is yours
to make, and without going through a site survey, I or you
have no way of knowing for 'sure' if you have a safety problem
or not. The thing is, it never hurts to be safe, but the
opposite can cause problems.
Everyone 'fudges' to some extent. What I would consider a
reasonable risk, may not fit your way of thinking, and the
same the other way around. I can't tell you if your safe, or
not...
'Doc

Hi Ralf,

>You write that a loop mainly reacts to the electric field component at
>some distance. Is there an easy explanation for this ?

As we all know, electric fields and magnetic fields both must occur in
EM radition. If one is zero, the other is also zero.

Any antenna, even the small loop antenna, has all fields. It's just
that very close to the antenna the magnetic induction field dominates
(unless you move up near the capacitor, where the two ends have a
large potential difference and the electric induction field will be
quite large in a small area) the radiation and the electric induction
field.

But as you get back just a small distance, things rapidly change.

I believe the variation in field impedance is cause by phase shift and
attenuation of the combined fields radiated and induced by the
antenna. It is a very real effect.

Without that transition (which looks like a standing wave) the antenna
would never reach the limbo all antennas reach in the far field, where
you can't tell one from the other except for the strength differences
between them.

>I always thought that a small loop is reacting to the time derivative of
>the magnetic flux passing through its area. Seems I'm wrong. I know there
>is a thing called 'antenna effect' responsible for the coupling of the
>loop to the electric field component.

While the loop has a low impedance, remember with every time-varying
magnetic field there is a time varying electric field. At any
distance, they are essentially equal.

That's why small loops can be calibrated to read electrical field
strength. They read it accurately as long as the loop is some distance
from the source.

Right against something, where the induction field dominates, the
small loop will couple quite heavily to magnetic fields. Move it back
a bit and that all changes.

The shield on a small loop isn't a shield at all, it simply is the
actual antenna. All the shield does at the operating frequency of the
loop is allow us to improve the balance of the loop if we ground the
shield properly, at the electrical ceneter of the shield.

Ground the shield off center, or at one end, and you can actually INCREASE the antenna effect of the loop! Some articles show the shield grounded at one end, and the user would probably be better off with no shield at all than the improperly configured shield.

>The german equivalent to the FCC demanded that you measure both the >magentic and electric near field to ensure that you are withing the limits >of the allowed near field strenghs. It is mainly this observation that brought me to the idea that the >reverse is also true and that the loop mainly responds to the magnetic >field component. Is there any literature about the effect you mentioned ?

I think Roy Lewallen might have some stuff, but I don't want to put him on a spot. I have some stuff Roy sent me.

What the DOC does in your country makes sense, because they are talking about right next to the antenna. It also could be a physically large antenna.

>When I had up my RX loop for 80 and 40 metres, I could only compare it to >a piece of wire in the attic (20 m long). The loop was in my bedroom close >to the wall (I put nails into the wall to hold the wire). I think there is no good or bad antenna (only a better or >worse one), it's just what you compare it to.

It does not surprise me one antenna hears less junk than another when the noise and antennas are close together. But you can be sure the TV sets are using a longwire antenna (the power line and the antenna leads) as an antenna. It is the characteristic of those WIRES and the distance to those wires that sets the field impedance of the noise close to the wires.

The only thing that surprises me is why people think noise or unwanted signals are somehow always "electric" and good signals are always "magnetic". Perhaps it is because we call the noise "electrical interference".

In any event, you can bet all those long low wires with multiple grounds mainly radiate with a low or modest field impedance, and that field impedance varies all along the wire. So why would or should anyone expect one antenna to be any better than another for discriminating against those signals except for the effects of placement around those wires and near-field directional differences in the antennas?

I can hear Europeans quite nicely on a one foot clip lead sitting in my room on 160 meters and 80 meters. If I use a small loop in the room, my computer wipes out the signals. I'd bet in the next room, the effect is entirely different.

>Is your beverage better than a single vertical ?

Of course when I'm receiving a signal in the favored direction of whatever Beverage I'm using! It is directional and hears less noise from unwanted directions. But the same Beverage has LESS S/N when receiving in directions other than its favored direction compared to a simple vertical.

>I don't know what the
>directivity of your vertical array is and how long your beverages are, but
>if the directivity is comparable then your judgement is no surprise, at
>least if you ascribe the 'noise suppression' of the beverage to its
>directivity.=20

My vertical arrays essentially use four primary verticals spaced about 5/8th wavelength broadside and 1/4 wl endfire (some arrays use 1/8 wl endfire spacing) . If you look at the patterns of such an array, with proper phase delay, it is very clean and much narrower than a Beverage even multiple wavelengths long.

The verticals, because they are more directive, are often several dB better than the Beverages for S/N ratio. As a matter of fact, four verticals in a 5/8th by 1/8th wave area (330 feet by 70 feet) normally exceed the performance of three Beverages 500 feet long and spaced 300 feet apart broadside. Those Beverages occupy a 500 foot by 600 foot area, and are virtually never better.

The advantage is especially apparent when conditions are unstable, because even at distances of 1000 feet (two wavelengths) the arriving signals are almost never in a stable phase or level relationship. The fact phase and level vary constantly prevents using an array occupying an area larger than 1000 feet to receive, because the ends of the antenna can be out-of-phase with each other and cancel! This happens randomly, and the effect is the fading of the signal greatly increases.

Only under the conditions of the most stable ionosphere can the antennas all be combined into one large array.

That's why my original 3 wavelength Beverages are now cut down to 1 wl, and multiple antennas are used.

What I did to solve this problem is use multiple phase-locked receivers on small arrays (maybe 500 feet by 300 feet area) separated by thousands of feet. Each receiver feeds an audio channel that I pick with a switch. I constantly rotate the switch to pick the best two channels to feed my stereo headphones when a signal is marginal.

I started the story on tower.htm which is linked from the top of my home
page.
It has a log way to go, but there are a number of pics. A couple have to be
replaced with thumbnails and the large versions linked to are unformatted.
Meaning that on a smaller screen, or with anything less than 1200 X whatever
they are huge. Get to se a bit of detail though <:-))

If the weather turns crappy, which it is in general this time of year, I may
get the thing finished up in about a week. I really have had to dig for
some of the pictures.

I currently have over 12,000 digitized and cateloged (kinda, sorta). My
filing system needs a bit of work. I currently run the negative strips
through a scanner and do them at 300, 600, 1200, and 2400 dpi. (No, I don't
put the 2400 ones on the web <G>)

Reminds me of when I had a pet crow.
He was known for sitting at the base of the back window and hooking his
claws around the trim and going for a ride.

One of the locals got his car up above 80 and there was that crow sittin'
back there looking in with claws hooked and tail braced.

Man, but I wish I had a picture of that!

Then there was the time he used the broad back of my dad's dog for a landing
field. My dad said the last he saw of them, the dog was running flat out
across the bean filed with the crow riding. Nuther Kodak moment missed.

Course this was a *few* years back. OK, quite a few.

Ok, here is the scoop. I am putting up my first ladder line fed antenna. I am blding a 160 meter dipole and want to feed with ladder line. Items of consideration please:

1) I have 100 ft of ladder line.. Don't need that much. Should I cut to needed length?
2) My shack is covered in sheet iron. I have windows. Is this a problem ? If so, how do i deal with it?
3) I am somewhat of a coward so antenna will be at abt 30 feet since I am a coward and won't climb any higher. Think this is ok?
4) I am using 12 gauge insulated wire because of an abundance of trees. Will run thru a couple of them. Problem with insulation, gauge of wire? Can I load the amp up with this?
Tnx and pls email with thoughts

Bill

Resonance is the freq where IM (z) is zero. This seldom corresponds to the frequency of best S11 for a 1/4 wave patch. It is off, roughly, by 2-5% if a generalization must be made.

The true issue is the frequency of maximum gain; getting that to be the freq of best S11 is usually the desired result.

Dave, in addition to the previous email - I had a Senior Moment and
forgot to mention it - why not try the antenna and see how it works.
Might not be as bad a performer as the appearance would suggest.

I would disagree with this, or at least with your terminology.

The transmission line impedance, either actual or what the amplifier sees, has nothing to do with the waves that travel in the transmission line. What it will effect, is how much power is loaded from the amplifier into that line.

By the same token, the impedance that the amplifer sees will only be Z0 if there is a perfect impedance match between the line and the load.

You may have meant/said that above - but it is unclear to me based on what you wrote.

Reminds me of the time years ago when I was steaming along 'bout 75 MPH early one morning on a deserted rural highway in my 400 cu in Grand Prix and came upon a couple of crows on the shoulder of the road. Of course they flew up when I approached, as they always do, but one unfortunate fowl chose to fly right down the middle of the road, directly in front of my fastmoving machine, at just enough altitude for the car to pass underneath him. But his airspeed was way to low to outrun the old Pontiac.
Unfortunately for him, I had a 5/8 wave two meter whip on a stout magnet mount base sitting right in the middle of the roof of the the old boat. The whip smacked him hard where his tailfeathers met his posterior, and the antenna flew from the roof, and the 'winged' bird sailed out of sight, off into a deep ditch. I got the rig shut down, and stopped to retrieve what was left of the antenna-but there wasn't much left except the magnet attached to the coax, dangling behind the car. The whip and the bird were long gone. Melded?

Source record: 175820

I acquired a used R-7000 recently. I have it sitting on a 10 foot mast at the edge of some trees in the backyard. It is set up with a "hinge" a bolt through the support mast, so that I can tilt it over for adjustment. After three adjustment cycles, I've got it under 2:1 on all bands. It has now become my preferred antenna, as it doesn't need any tuner assistance to match any band. The exception is 40m, where you will need to decide if your are phone or cw, adjustment is narrow but to be expected with a multiband vertical. 10m is very broad and well below 1.5 to 1 across the band.

The manuals are on the manufacturer's website.

It is a great dx antenna, the farther away the station, the better it works. I've also done some qrp work with it. Nice to have a dx station come back to a 5 watt signal! I don't have a beam and tower here, so verticals are my most satisfactory solution so far.

Good Luck,

Bill, W4WNT

A quick model placing it over an average height of 25' shows a resonant feed resistance of 55 Ohms at 7.060 and 96 -j154 at 21180. The antenna is resonant at 21.95 on 15M with a feed r of 113 Ohms (2.25:1). Try the vertical wires at the 11' points and see what you get- this should have a minor if any effect on 40M performance. You might also try getting rid of the balun and replacing it with a choke balun. Voltage type baluns will almost certainly have an effect on the feed Z as they are obviously not perfect 1:1 transformers except perhaps over a small frequency range.

Hi,
your corret the nylon (I find that a little too stretchy) was only 1/2" and
the Darcron was only 3/8" so it may be that the size is the factor here..
the reason for the need to replace the ploy is that it will break down in
sunlight after awhile.. here in western Maine I have one peace that's been
up for about 8 years with little sign of deterioration. but it is pretty
much sheilded from sunlight.. I'd say 4 to 5 years would be a good guess as
to how often 3/4" should be replaced if in direct sun.

Hope that's of help..

Quite true, and as one goes higher in frequency, the effect of the
second shield becomes much more important. I doubt that many hams use
RG-214 at 10 GHz, but it is quite common in a test lab. Once where I
was working someone mistakenly used a length of RG-213 instead and
the leakage was sufficient to cause a noticeable increase in insertion
loss.

2952. power to antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-23 00:00:00 UTC
From: ron biggerstaff <rbigg@pcola.gulf.net>
Message-ID: <t1qkd6mfeuv4d8@corp.supernews.com>
Source record: 175824

I noted the recent discussion over whether or not reflected power is real or not, and was reminded of a similar discussion I was involved in awhile back. As a result of it, I gained some useful information that others might be able to use.

I had noticed that while settting my antenna tuner controls for minimum swr, there was oftentimes a split between minimum swr settings and max forward indicated power. In those situations, I could have one or the other, but not both. Probably, a number of you have also observed this effect, at one time or another, in one situation or another. So, I asked the question as to which way I should tune. Should I opt for max indicated forward power, or go for minimum swr? Which setting would give me more soup out the antenna?

The answer I got back was very interesting, and was something I had not known: forward indicated power on most swr meters consists of actual forward power plus reflected power; i.e., we're really reading the summation of actual forward and reflected power on the meter scale. I thought about this a bit, and then realized that, if this was true, then it means that by tuning for minimum reflected power, we always maximize actual forward power, regardless of the indicated forward power reading. I then asked this question, and was told that was correct. The final conclusion was that for practical purposes, although the indicated forward power side of our swr meters really isn't very useful in many situations, it can be a useful indicator in others.

It got me to a point where I had what sounded like a satisfactory explanation as to why I was seeing what I did, and how to deal with it. The practical side was what I cared about. That's something we can use to get the most soup heading out toward the antenna. Today, I rarely switch over to the forward power side of my tuner.

I don't know how tall your 25G tower might be but whatever it is considering that it's for 160 it's gonna be big and guyed. Which is to say the weight of all those 25G sections plus the vertical reaction forces imposed by the guys from wind loading are absolutely going to put a very large compressive load on whatever insulators you come up with. Without being able to deal with it quantitively my strong suspicion is that there ain't a plastic out there which can handle the kinds of loads you'll have, including any of the flavors of fiberglass. Unless the insulators are outlandishly huge and properly designed. Ceramics on the other hand have enormous compressive stress limits, are better insulators and perhaps more importantly do not suffer long-term creep deformations like the plastics do. If Rohn thought plastic insulators were a good idea they would be using them. They don't and I agree with them.

<Snip>

Another interesting thing to realise, is that minimum indicated VSWR doesn't always occur at a purely resistive 50 ohm setting.

As those who can use the Smith Chart (which I've never really got the hang of) can show, a combination of inductive and/or capacitive reactance can be present along with the resistive component. Most VSWR meters wont show you this.

I've also been quite entertained (maybe I'm easily pleased?), when using an antenna analyser and a VSWR meter, to see how many 'false' matches I can make if I relied on just the VSWR meter. There seems to be an almost blind faith in what's been shown on the meter by some people. It's also a 'good game' to put two VSWR meters in series, and see what difference there is. One Amateur, who I knew, called his VSWR meter a "guessing stick".

Mind you, as someone else has said before, in the 'good old days' people didn't worry about such things, they just got on and worked other Radio Amateurs. HI! If they can hear you, and you can hear them, what difference does it make? In my hotel room this week, I can get a wonderful indicated VSWR reading, by twiddling the knobs on an ASTU, but I can't hear many people, so I'm not working anyone this week. That's because, the antenna is inside a building, and very little RF is getting in or out!

Cheers de Dave (G0DJA)

Cecil, why are you dragging the special and worn-out cases
of Zo and conjugate matches into the discussion ?

Are you saying no standing waves are produced on the line
when power reflected back from the antenna towards the
transmitter meets a mismatch at the junction of the line and
tuner (it always does), and (the crux of the matter) that
varying the tuner setting has no effect on those particular
waves ?

Reg.

I'm saying that the purpose of a Z0-match is to create two sets
of complimentary reflections the sum of which is zero. Therefore,
there is no reflected energy on the coax between the transmitter
and the tuner. The purpose of the Z0-match is to keep reflected
energy from reaching the transmitter.

The goal of life is to keep living. Committing suicide destroys life.
The goal of tuning is to establish a Z0-match. Varying the tuner setting
away from a Z0-match destroys the Z0-match. Of course, it has an effect
but it is not the desired effect. The desired effect is to completely
cancel the reflections at the Z0-match point thus causing the scalar
reflected power to be routed to the antenna.

> always occur at a purely resistive 50 ohm setting.

==========

Dave, you can say that again - minimum SWR vs frequency
hardly EVER occurs at a resistive 50-ohm setting.
Furthermore, the indicated SWR usually refers to a
transmission line which doesn't exist - so who cares about
SWR ?

Reg

PS. What the meter really tells us is the reflection
coefficient of the load presented to the transmitter
relative to 50 ohms. Now that IS useful to know.

Yep, I agree the tuner can be mistuned. But when it is tuned
properly, it *effects an absence of reflections* between the
tuner and the antenna. That's the Z0-match point.

You should tune for the maximum difference between forward power and
reflected power. The difference between forward power and reflected
power is what is going into the antenna. On my IC-706, the maximum
difference between forward power and reflected power seems to be
when reflected power is zero.

If the SWR meter reads forward power and reflected power then
the difference in those two readings is what makes it into the
antenna (neglecting feedline losses).

Thanks to everyone who replied to this post. I found your replies quite useful. I've decided on a set of books to study for the tech, general and extra exam. After, I get the extra certification I would like to start designing and building RF circuits. I've found two books (one which is quite old) on rf design. Could anyone recommend these or other books taht talks about RF design for a person with an extra cert?

1. Introduction to Radio Frequency Design (Radio Amateur's Library, Publication No. 191.) by W. H. Hayward
Paperback Bk&disk edition (March 1995)
Amer Radio Relay League; ISBN: 0872594920

2. Practical Radio-Frequency Handbook
by Ian Hickman
Paperback - 320 pages 2nd edition (October 1997)
Butterworth-Heinemann (Trd); ISBN: 0750634472 ; Dimensions (in inches): 0.81 x 9.22 x 6.26

I don't know how tall your 25G tower might be but whatever it is
considering that it's for 160 it's gonna be big and guyed. Which is to
say the weight of all
those 25G sections plus the vertical reaction forces imposed by the guys
from wind loading are absolutely going to put a very large compressive
load on
whatever insulators you come up with. Without being able to deal with it
quantitively at this point my strong suspicion is that there ain't a
plastic out there which can handle the kinds of loads you'll have,
including any of the flavors of fiberglass and don'r even think about
any of the thermoplastics and/or teflons. Unlesss the insulators are
outlandishly huge and properly designed. Ceramics on the other hand have
enormous compressive stress limits, are better insulators and perhaps
more importantly do not suffer long-term creep deformations like the
plastics do. If Rohn thought plastic insulators were a good idea they
would be using them. They don't and I agree with them. I also agree that
$1,200 is a real bite out of your wallet but in the final analysis I'd
go with the Rohn hardware grousing the whole time. And watch how you put
the tower up if you do go with the Rohn insulator section, the
insulators are real fussy about how much abuse they will tolerate during
tower erection.

I certainly have one that is useful for mobile measurements.
But how do you guarantee that your field strength is measuring
horizontal far field in the direction of propagation? How do you
know it's not measuring minor lobe near field vertical radiation?

What I am most comfortable with is getting the maximum power
to the antenna and trusting a modeling program for the radiation
pattern shape. But it is an interesting question.

Actually, I said "what's going *into* the antenna". Could also be what's
going into a dummy load so, no, I'm not saying it results in maximum
field strength.

After getting maximum power to the antenna, I trust the modeling program
to tell me what the radiation pattern is. Based on experience, I haven't
ever found a reason to doubt that approach.

I know a ham who tunes for maximum field strength. When I ask him if
that's near field or far field he says he doesn't know. When I ask him
if he's measuring horizontal radiation or vertical radiation, he says
he doesn't know. When I ask him what is the take-off angle of the radiation
measured by his FSM, he says he doesn't know. That seems like a lot of
unknowns to me.

2970. No such thing, was: Where does reflected power go?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-23 00:00:00 UTC
From: dysart@nortel.ca
Message-ID: <8vis99$4f4$1@bcarh8ab.ca.nortel.com>
Source record: 175900

Allow me to provide the simple analysis that caused me to conclude
that there is no such THING as reflected power.

It seemed to me that any acceptable explanation of where 'reflected
power' goes should work:

a. at a frequency of 0 hertz.
b. with the transmission line open-circuited.
c. with the transmission line short-circuited.
d. with any generator. In particular, it should work if the
generator is replaced with:
d1. its Thevenin equivalent circuit.
d2. its Norton equivalent circuit.

Since these boundary conditions lead to fairly simple arithmetic,
it can all be done in your head.

Let us start with a transmission line (TL) of impedance 50 Ohms,
length t (the time for one way propagation along the line) and a
generator with an output impedance of 50 Ohms.
Leave the right end of the TL open-circuit.
Set the generator to 50 V (into 50 Ohms) and attach it to the left
end of the TL.
One Amp begins to flow into the TL.
This charge propagates down the TL creating a voltage step of 50 V.
To the right of the voltage step, no current is flowing and the
voltage is zero; to the left of the voltage step, 1 A is flowing
and the voltage is 50 V.
At time t, the voltage step reaches the end of the TL and the current
can flow no further since the TL is open-circuit.
But charge is still arriving so a voltage step from 50 to 100 V occurs
which propagates back along the line.
To the right of this step, the voltage is 100 V and no current is flowing;
while to the left of the step, the voltage is still 50 V and 1 A is still
flowing.
At time 2*t, this voltage step has propagated all the way back to the start
of the TL.

While the line was charging, the generator was providing 50V * 1A -> 50 Watts
into the line. This continued for 2 * t seconds.

Now the TL is fully charged to 100 V and no current is flowing anywhere in
the line.
The generator is no longer adding energy to the TL.
The energy delivered to charge the TL is stored in the capacitance of the TL.
Since the current is zero everywhere in the TL, there cannot be energy flow

anywhere in the TL so the power must be zero.

And yet believers in reflected power would like me to accept that there is
50 W of forward power and 50 W of reflected power for a net 0.
But I can easily see that there is no power flowing in this TL, anywhere.
It is only a charged capacitor.
As for the 50 forward and reverse, one could just as easily argue that it
is a megawatt forward and reverse. It yields the same result.

So I conclude there is no such thing as 'reflected power' because it does
not explain the 0 frequency situation and therefore the question 'Where
does the reflected power go?' is meaningless.

To carry the study a bit further we can ask what is happening in the
generator after time 2 * t.
If we assume a Thevenin circuit for the generator it is dissipating 0 W.
If we assume Norton, it is dissipating 200 W.
Dissipation in generators depends more on generator design than 'reflected
power'. Any argument that 'reflected power' is dissipated in the generator
can easily be shown to be false by substituting Norton for Thevenin or vice
versa.

For a short-circuited TL after 2 * t:
- the voltage will be 0 V everywhere
- the current will be 2 A
- this still leads to 0 W
- the energy is stored in the inductance of the TL
- Thevenin will dissipate 200 W
- Norton will dissipate 0 W

The so called 'reflected power' is the same but the dissipations are all
different.

Some might argue that it is the 0 frequency case that is special and that
'reflected power' makes sense for non-zero frequency.

Let us consider an open-circuited TL of several wavelength driven by a
matched generator.
After time 2 * t there is a standing wave on the line.
At the end of the line the current must be zero since it is open-circuit.
Every 0.5 wavelength back from the end the current is 0.
0.25 wavelengths from the end the voltage is 0.
Every 0.5 wavelength back from there, the voltage is 0.
We know that power is voltage times current.
Since every quarter wavelength back from the end, either the voltage or
the current is always 0, the power must be 0, so there is no energy
flowing across these points.
If there is no energy flowing, there can not be any 'reflected power'
flowing unless 'reflected power' is not actually a flow of energy and
therefore not a power.

And this is the answer. 'Reflected power' results from a computation
that yields a dimension of power but does not result in anything that

is real. This mathematical convenience does have value though, because when it is combined with another computation yielding a non-existent 'forward power', one can compute SWR and net delivered power.

This is an example of analysis where the intermediate results have no physical meaning but the final result is useful. Remembering the type of circuit analysis (I can not remember the name) where all voltage sources are set to zero and then one-by-one they are set to their desired value and the resulting currents are computed. Later all the computed currents are summed to find the real currents. While the intermediate computations yield values with dimensions of current, these currents do not physically exist. A simple example will suffice.

Consider two 10 VDC sources whose negatives are grounded and whose positives are connected with a 10 Ohm resistor. Analysis yields 1 Amp flowing clockwise and 1 Amp flowing counter-clockwise for a net of 0 A in the resistor. The final answer is correct; the intermediate answers do not represent currents which are flowing.

To make this very clear, replace the 10 Ohm resistor with a zero Ohm resistor. Result: infinite current clockwise, infinite counter-clockwise, but the net is still correct at 0.

Never assume that intermediate results, no matter how useful to solving the problem, represent real things.

Hi Roy,

You Make a good Point.. I've used this method for 10 years in in White Pine Trees.. Using Large 3/4 inch Polypropaline rope. The Black Stuff is best.. (It has to be replaced every so often but it cheap around here because it's what the fishermen use for their nets and Lobster pots.) I use one rope up over the branch and then attach that to another rope with a pulley.. that way even if the rope should seize up there i can still get the antenna down.. But at least in the White pine had it seize yet.. I have had nylon and Dacron seize up there.
For what it's worth.

The open-circuit generator volts is 100 V.

The return current is -1.0 A (note the change of polarity). The net current to the right of the returning wave is 1.0 - 1.0 = 0.0 A. To the right of the return wave the power is 50 W forward and 50 W reflected. This is what a directional wattmeter would read. To the left of the return wave it reads 50 W forward and 0.0 W reflected.

OK. The wattmeter reads 50 W forward and 50 W reflected, for a net of 50 - 50 = 0.0 W

> And yet believers in reflected power would like me to accept that > there is

> 50 W of forward power and 50 W of reflected power for a net 0.

The wattmeter in your example reads 50 W forward and 50 W refelected.

> So I conclude there is no such thing as 'reflected power'

It has been said several times (suggest you review) in this forum that because of the way it is designed, the wattmeter (an impedance bridge) is in actuality responding to the voltage *across* its output terminals and the current *into* its output terminals. It does *not* respond *directly* to a power value. The

thing is that the meter scale is marked in terms of watts. The concept of forward and reflected *power* is convenient. One reason is that these two values can easily be used to calculate SWR. And when the return power reading is zero, the true load power is what is the forward meter reads. And the actual load power is always forward minus reflected. When we talk about forward and reflected power we are actually thinking in terms of what a directional wattmeter scale reads. But the real action is in the forward and reflected voltage and current waves.

> 'Where
> does the reflected power go?' is meaningless.

OK. That has been said several times also.

> To carry the study a bit further we can ask what is happening in the
> generator after time 2 * t.
> If we assume a Thevenin circuit for the generator it is dissipating 0 W.
> If we assume Norton, it is dissipating 200 W.

Not OK. The conversion from Thevenin to Norton is not that simple. In the steady state the Thevenin current is 0.0 because the Thevenin impedance is infinite (generator plus line). The Norton current must therefore also be 0.0 in the steady state. The condition "no current flows" must always be satisfied when the load is an open-circuit. Stand at the end of the line and look back. We must see 0.0 A in both cases. In other words, Norton and Thevenin *must* produce identical results or they are not equivalent.

Put up your dipole as high as possible. Centre feed it via
450-ohm or 600-ohm balanced line. Connect a 1:1 choke balun
between end of line and the tuner. Connect the tuner
directly to the transceiver. It will work OK with a 25
metres long dipole.

But it will tune up more easily if you increase length of
dipole by bending both ends either sideways or downwards by
90 degrees.

You can afford to be only 50% efficient, 1/2 S-unit or more,
before anybody notices your signals are getting weaker.

To analyse performance of dipoles plus feedlines plus
tuners, download program VARNEY.exe from my website.
Download in a few seconds. Not zipped up. Run immediately.

Just put up your dipole and enjoy the DX.

Does a pendulum clock keep time when the pendulum is swinging? How about when the pendulum is not swinging? An AC system is simply different, in many ways, from a DC system.

Reflected power is a *dynamic* exchange of energy. It simply doesn't exist under steady-state DC conditions. Note that reactance is either zero (short) or infinite (open) at 0 frequency. Does that mean there is no such thing as reactance?

We know that reflected power exists because it causes additional losses in the transmission line over and above the matched line loss.

That's the beauty of a Z0-match, Reg, the internal impedance of the transmitter doesn't matter if no reflected energy is allowed to reach the transmitter. That's the basic function of an antenna tuner - to keep reflected energy from invading the transmitter. A Z0-match is all we need. We don't need a conjugate match.

The Hamstick is the lesser of two evils on 80m. But an
80m Hamstick should not be used on the higher bands.

One runs into a condition known as self-resonance which
is a series resonant condition where vast amounts of
energy are exchanged between the inductance and the
capacitance of the antenna resulting in massive ohmic
losses.

IMO, a 102' whip plus SGC would be a superior mobile antenna
to an 80m Hamstick plus SGC when used on 20m, for instance.

Not really applicable to antenna systems, but, to reduce noise, control
systems use double-shielded cable with the outer shield tied to earth
ground and the inner shield tied to system common.

> identical results or they are not equivalent.
>
> Bill W0IYH

There is something else that I overlooked. In an RF power amplifier the output series resistance (Thevenin) or the shunt conductance (Norton) do not dissipate power. They are almost entirely lossless, *dynamic resistances* that are due to a *negative feedback* effect within the amplifier tubes/transistors. This idea has been very well established, but is still having some acceptance problems for some folks.

The result is that in your example, the power dissipated in both the Thevenin and Norton circuits are 0.0 watts. The current generator is 2.0 A and develops 100 V across a 50 ohm *dynamic resistance*. In the Thevenin the 50 ohm generator *dynamic resistance* dissipates 0.0 W and the output voltage is 100 V. Both circuits are equivalent *inside* the circuit..

In ordinary situations of real resistors your comments about Thevenin and Norton do illustrate a problem. In general, the equivalence can only be measured by the results that they produce *beyond* the equivalent circuit. The insides of the equivalent circuit may not produce the same actions, just as you said.

The rule is that we are not supposed to look inside the equivalent circuit, but only look beyond the equivalent circuit, to see how the rest of the circuit is behaving.

recently built a 40 meter dipole from 12 gauge "flex" and 50 feet of rg8
with w2au balun at center.
center hung at approx. 30 feet and ends at approx. 20 feet. don't remember
what the final pruned
length was but appears to be resonant at approx. 7060 khz where swr is
1.4:1. assume this represents
difference in impedence between 50 ohm coax and whatever feedpoint impedence
happens to be.
works fb. no tuner.
my intention was to use this antenna on 40 and 15, so expected to see some
reasonable match around
21180 (7060 x 3rd harmonic). unfortunately, swr is no better than approx.
4 or 5 to 1 across entire
15 meter band. had i discovered a match somewhere, i planned on adding
capacitance hats about
a third of the way out from center to bring it back down to the cw portion
of 15.
will the capacitance hats still correct this? suggestions? thanks in
advance..

The only thing I would add would be to get a copy of the ARRL Handbook
for Radio Amateurs. It starts with basic theory, and advances to
theory that is quite complex. This would be a good reference to have,
in addition to the ARRL License Manuals. I'd get all three ARRL
license manuals -- technician, general and amateur extra.

I don't know why people get sucked in to thinking there
is no such thing as reflected power.

Anyone who has ever done any TDR work knows that
to be false.

Dave,

You mention that you've had nylon and Dacron seize, but
that the polypropaline never seized. I wonder if that is a
function of the size of the material (3/4) or the type. Did
you try 3/4 nylon or Dacron, or were they of smaller
diameter? You also mentioned the need to replace the
poly from time to time - can you give an estimate of
how long it lasts, and what is the main cause of deterioration?

Abrasion is my main problem. Someone recommended
kernmantle rope - but it runs about $130.00 for 50 meters.
It is mountain climbers rope and a lot stronger than needed.
So my intent is to haul new rope up periodically, replacing the
old stuff. Once it seizes, I'm sunk - but as long as it "rides" on
the smaller ends of the branches, it doesn't seize. "Fat" poly
might be a great way for me to go.

There is no doubt about this, I did not tell different (hope one could not misinterpret me in this direction).
Nevertheless there are 'antennas' which mainly respond to the magentic field component. The most famous example is the atomic transition that is used to build the cesium atomic clock, which is mainly produced by the interaction of the magnetic moment of the nucleus and a time varying magnetic field. I don't know if the atom knows about the Maxwell equations, but I know that it mainly responds to the magnetic field.

In opposite, the sodium D light used in street lamps is mainly due to interaction of
the electrical dipole moment with the electric field.

Does that mean that the 'magnetic' loops used for measuring the magentic near field component are useless ? There was a series about constructing a near field probe in german cq DL magazine last year mentioning and testing the H/E relation in TEM chamber simulating a plane wave.

In the far field E and H waves are totally equivalent (they must be because of energy conservation). In the near field both parts are necessary too, but one goes like 1/r^2 while the other goes like 1/r^3. Since both functions never reach zero, this is no contradiction to the Maxwell equations.

> While the loop has a low impedance, remember with every time-varying

This only holds for the far field component.

> That's why small loops can be calibrated to read electrical field
> strength. They read it accurately as long as the loop is some distance
> from the source.
The calibration of the magnetic probe to read electrical field strength
relies on the assumption H=E/377 Ohms, which is true for the plane wave
aka far field. It does not work in the near field.

I agree.

> What the DOC does in your country makes sense, because they are
> talking about right next to the antenna. It also could be a physically
> large antenna.
I don't know the cited study myself. In germany you have limitng
values for the magnetic and electric near field per band. The normal,
accepted (though inaccurate) procedure is to put ur power and antenna gain
into the far field formula and see what safety distance comes out. But in
some cases you need accurate near field calculations or measurements. For
magnetic loops the study is said to show that the main limitation is the
magnetic field strength, at least if you get closer than 6 or 7 metres to
the loop (on 40 metres).

> The only thing that surprises me is why people think noise or unwanted
> signals are somehow always "electric" and good signals are always
> "magnetic". Perhaps it is because we call the noise "electrical
> interference".
For the far field it makes no differences. But if your noise source is
using an 'electric' antenna and you are close to this antenna you will
mainly see the electric near field component: Of course this depends on
where you are relative to the transmitting antenna. Put a ten meter dipole
5 metres in the air and measure the electric and magnetic field strength
just below one end. According to what people who did it told me you will
be surprised that the equivalence between H and E known from the far field
does not hold. The E field is 'larger' (although we compare different
units of measure here). This means you can not measure the magentic field
and calculate the electric field, you have to measure both.
If you are right and the fields are always equivalent, which probe do I
have to believe in this case, the electric or the magnetic one ?

Interesting solution.

By the way there was another article about a broadband active antenna
using two magentic loops perpindicular to each other. I know four people
who built this antenna and say they have better S/N than with active
electric antennas (although the signal difference is something like 20 dB
on a spectrum analyzer). Two of the four comparison antennas are produced
by Rohde und Schwarz company and have IP3 of 30 dBm and NF of 5 dB.
The magnetic antenna's active part has similar characteristics (the NF is
around 7 dB and IP3 maybe little bit higher.

Roy:
In the average Ham/SWL application, you are probably correct. However, in locations where the runs are long, and all kinds of other types of cables are in the same cable trays, it really makes a difference. Some measurements were performed on 100 foot runs of RG-58/U vs. RG-223/U several years ago, and if my filing system were organized, I could quote you the numbers, but there was a easily measurable difference. Today, the problem tends to be something like CAT-5 signal cables running along receive coax runs, and it doesn't take many feet of that to start showing up in the receiver input. A few feet of RG-58 running in the vicinity of some of the poorer computers will also produce measurable (and hearable) signals in a HF receiver.

Dale (W4OP) had some good suggestions and here are a few more.

The capacitance hats, situated about 1/3 of the distance from the feed,
should
work but I have, in the past, found them difficult to work with and hard to
adjust.

One suggestion would be to place another wire, in parallel with your current
radiator, that is tuned to 15 Meters. This will have some effect on your 40
Meter wire but if you tune the 15 Meter wire first and then the 40 Meter
wire,
the interaction should be minimum. Keep the second wire spaced from the
first
by about 6 to 12 inches. You could also configure it as a fan.

Another possibility is to use a trap. A trap could be placed at the proper
distance
for 15 Meters so that when you operate on 15 Meters the wire past the trap
is
isolated and not seen. On 40 Meters you will see all of the wire. A trap has
the
added effect of shortening the 40 Meter section of wire so, when you
initially put
the trap in, you will see the overall resonance of the antenna go down in
frequency.

I am currently running a 4 band (40,20,15,10) trap dipole and use no tuner. The
match is good across all of 40, 20, and 15 Meters and most of 10 Meters. I admit
that traps are not easy to work with but they worked the best for me and I get more
band coverage in less space.

Good Luck

> consistent with the hypothesis proves the hypothesis.

It's not just a single case. I've shown that with a 100 joules/second
generator looking into a one-second long transmission line with an SWR
of 5.83:1, the energy stored in the transmission line is 300 joules.
Take away the dynamic generated energy and you have 200 joules left
which is reflected power going both ways and causing additional losses.

Reflected power can be seen on a TDR. Reflected power can be used to
boil water using the load tied to a circulator.

Exactly how much of reality are you capable of ignoring?

You can cook your hand using the nonexistent reflected power
collected by a circulator load resistor.

Yes it is and I'll be glad to explain. Assume a lossless unterminated
transmission line that is 2.5 hours long. Pour a kilowatt of DC into it
for five hours. Disconnect the transmitter and grab the conductors with
your hands. What is frying you with no other source of energy attached
is reflected power.

With a vertical antenna, not much radiation is aimed directly
at the ground. Most of it is radiated parallel to the ground.
But with a horizontal antenna, things are rotated 90 degrees
and a lot of radiation is aimed directly down toward the ground.
Ever try to use a FSM to adjust for minimum F/B ratio on a
horizontal beam?

You are missing the point OM. You can NOT have a time-varying electric
field without a time-varying magnetic field.

>Plus, look at the loop antennas used to measure RF. They're not only balanced
>(one of the tests for balance is that they should NOT respond to an E-field)
>but shielded from E-fields. That shield is not connected to the feedline, and
>is cut so that it does nor even provide a path for induced currents to flow. So
>THAT is not the antenna. Also, taking it off doesn't reduce the signal.

You can NOT shield a loop from a time varying magnetic field. All the
shield will do is act as the antenna.

The shield becomes the antenna, and the winding inside the shield
simply couples to the shield's inside with normal coupling involving
both fields.

The shield's inside (assuming it is more than a few skin depths thick)
couples to the outside of the loop because it has a direct connection
at the open shield ends, where the current spills over the edge.

There is an electric field across that junction.

Taking the shield off can actually increase the signal, because the
path length of the current is decreased.

That's how a sheilded loop works, no matter what misinformation is
circulated through popular rumor. You can find that information
documented in later copies of Reference Data for Radio, as well as
other technical publications.

What is meant by a 'better ground' ?

A better ground need not be one with a higher conductivity.
There are circumstances when a higher resistance ground is
better. As exemplified by an arid sand desert. Such soil
is a very good low-loss insulator. Almost as loss-less as a
copper sheet.

Thanks, Cecil. I have a reason to ask. My QTH is on what is locally called a 'Mountain", but is really the southern tip of the Cumberland plateau. This is old seabed, eroded, so the hills are flat on top, with valleys cutting into the table. In my case, the drop off to my west is about 300 ft away, and to the east is about 400 ft. This tapers to the south, so that there is a point about 1250 ft away. It is shaped like a triangle, with the edges dropping off sharply, about 300 ft in the first 1/8 mile, and almost 1000 ft to the valley floor, which is near the level of the Tennessee river. The river is at 600 ft above Sea level, and I am at 1600 ft.

THe whole terrain is broken up into valleys, so that, despite an 800 ft drop in between, I can see other points to the east and west, about a mile away, that are at my altitude. To the south, the next ridge is over 5 miles away. In winter, I can see the river, to the SE.

I am pretty isolated (nearest neighbor is 1/4 mile north) and, electrically, pretty quite. I have thought about getting a Terrain analysis, but don't know if it is worth it, except for curiosity satisfaction.

Do you (or anyone else) have an opinion about this kind of situation?

I have an Alinco DX70TH so naturally I'm keeping an eye on that one. Also curious about Smartuner, LDG, etc. They seem like a good idea for a versatile mobile/portable/limited-space system, but even I know you don't get something for nothing.

Main concerns: effectiveness, ruggedness, lightning vulnerability, compatibility.

Corry,
I'm sure you can think of a few of the "pro"s of this kind of
an antenna system. The "con"s that I can think of, off hand, are
that the effectiveness of such an antenna system depends on the
length of the 'whip', or radiating element. The shorter the 'whip'
part of the system, the worse the efficiency. The 'usual' six or
eight foot whip that comes with a few of the autotuners is just
worthless on most of the HF bands.
Another one of the "con"s is that your limited as to output
power.

His basic argument is that under steady-state conditions at a frequency
of zero Hz, there are no reflections. Therefore, reflections don't exist.

Due to my last posting about a ham question I have been spamed to death
from
using my real email address. Please send your reply directly to
VE7LWB@rac.ca

Here is my GPS question. I have a GPS handheld unit made by Lowrance. My
question is this, what frequency is the sat on that GPS runs on? I know
it's somewhere
in the gig range, but where about's 5Ghz?? 10Ghz?? 20?? or higher ?? I
know it's
up high as I can see the differance in the signal locks I get on the bird
from a clear
sunny day to a heavy cloudy day. On a very heavy cloudy rainy day out on
the boat I
get less birds I can get a signal lock on. I have also heard something that
there are
GPS units that run on frequencies in or around that 400 to 500 Mhz area. Is
this true
or was I being fed a line of BS ? And if there are ones in that range, who
makes them?
And any other info on it would be nice....

The load impedance for the PA is then 50 ohms pure resistive, which is what the rig was designed for. This suggests best efficiency and best cleanliness of the output sig.

Hi Cecil,

if the OM can be sure that all field strength he sees is radiated by the
antenna, that his method is correct since there is monotone relationship
between the power 'absorbed' by the antenna and the field strength (field
strength goes like square root of power). Anyway you have to be sure if
your field strength meter does not pick up feedline radiation etc. and
this unkonown remains.

George,

I agree some form of instrument is essential.

But what your meter indicates is not swr. It is a
reflection coeficient meter which should be scaled linearly
from 0 to 1.

SWR = 1 corresponds to RC = 0. SWR = Infinity corresponds
to RC = 1.

Let's scale the meter properly and call it it by its correct
name. And only one moving coil movement is needed.

There is not even a transmission line on which the indicated
swr is imagined to exist. Novices trying to understand the
technicalities are confused and misled by imaginary standing
waves on non-existent lines. As shown by questions posed to
this newsgroup.

In the year 2000 it is time the radio amateur handbooks were
expurgated. (Incidentally, the conjugate match should have
been allowed to remain.)

An additional clarification.Stand at the end of the line and look back. If the equivalent circuit is Thevenin the voltage is 100 and the resistance looking back is 50 ohms. The dissipation inside the equivalent circuit is 0.0 W.

If the equivalent circuit is Norton the voltage is also 100 and the resistance is also 50 ohms. But the dissipation inside the equivalent circuit is 200 W.

So the two equivalent circuits are equivalent when viewed from *outside*. But in your example the power dissipations *inside the equivalent circuits* are much different. This is a problem with equivalent circuits that says that we should not focus on what is going on inside the equivalent circuit, but should see what these equivalent circuits produce, outside the equivalent circuits

Yes, these are the intermediate values that the computations produce but
one does have to be careful about falling into the trap of believing
that these currents which sum to 0 actually exist.

[snip]
>OK. The wattmeter reads 50 W forward and 50 W reflected, for a net of 50 - 50 =

I agree that is what a wattmeter would read. Again readers, be careful
of the trap. Just because a wattmeter has a scale calibrated in watts
does not make those watts real.

[explanation of how wattmeter works snipped]
>But the real action is in the forward and reflected voltage and current waves.

I agree completely. I was attempting to make the inconsistencies of
'reflected power' clear without explaining how it was actually derived.
I accept its usefulness as an intermediate result in a computation.

I fear I did not write clearly here. I should have said: 'For the purposes of this thought experiment let's consider what would happen in a generator actually constructed using Thevenin's or Norton's circuit.' For these easy to compute examples, the conditions outside the generator will be the same, but the power dissipations inside will be completely different. I was attempting to demonstrate that computing 'where the reflected goes' using a Thevenin generator can easily be proved incorrect by substituting a Norton generator. The computed dissipations will be all different and yet it would seem reasonable that 'reflected power', if it existed, would not go different places depending on the circuit design of the generator.

I proposed 5 criteria that reflected power should meet and used two counter-examples to demonstrate that so-called 'reflected power' did not meet these criteria.

If you can demonstrate any flaws in my criteria or logic I will happily reconsider my position.

Remember though, that providing examples which are consistent with an hypothesis do not prove the hypothesis, no matter how many examples are available. Only a single counter-example is needed to disprove an hypothesis.

I believe I have provided that counter-example.

I agree and again apologize for not making clear that I meant: "Let's
analyze a generator constructed using Thevenin's or Norton's circuit."

Of course, there are few situations in the real world where one would
want to use these circuits. They are terribly inefficient.

The "dump resistor" does indeed get hot, so there is power in it. That is not the issue here. The issue is precisely this (one more time):

Power itself is not a basic entity that travels on a transmission line. Voltage waves and current waves are the entities that travel, and that is how mathematical analyses, for example Johnson's Equation 4.23 and his entire book, handle this subject. This conforms to the basic nature of a transmission line, which consists of distributed inductance and distributed capacitance, in which voltage and current are the basic players that decide what is going on inside the line.

At any location the "power" is *calculated* as the real part of the product of voltage and current. That is, real power is a *derived* number. This is what heats up the dump resistor (or the resistor in the reflected port of a directional wattmeter).

>is no such thing as reactance?

I considered that someone might consider DC and AC to be fundamentally different and that is why I provided the second counter-example. You are invited to consider it.

On the other hand you might wish to consider the following psuedo-AC-DC example. Turn the generator on for 5 hours and off for 5 hours and then on, etc. This is clearly an AC environment. I suggest that for the 5 hours the generator is on (minus 2 * t seconds) the system behaves exactly as I described for the DC case, but your objection can be removed because it is actually an AC example.

While I agree that "AC is different in many ways from DC", I do not find that to be the case with regards to so-called "reflected power", especially in the counter-examples I have provided which were specifically selected not to have reactive elements.

The assertion that "We know that reflected power exists because it causes additional losses in the transmission line over and above the matched line loss." is a classic logic flaw of assuming that a single case consistent with the hypothesis proves the hypothesis.

As a matter of fact they do exist, and a directional ammeter in the line at that point would show them. A directional voltmeter would show two 50 V waves, whose readings add to 100 V. The algebraic sum of the two currents waves is zero. The transmission line is a linear circuit, and it is possible for two distinct currents to flow in opposite directions at the same time. This kind of thing goes on all the time.

> [snip]
> >OK. The wattmeter reads 50 W forward and 50 W reflected, for a net of 50 - 50 =

Not true. The wattmeter readings in the forward and reverse direction are, in fact, true watts. It is only the difference between the two (0.0 in this case) that is delivered to the load. And the reflected reading is the true wattage that is delivered to a *50 ohm* dump resistor.

As I have mentioned previously, what is going on inside the equivalent circuit cannot be used as part of the explanation of transmission line behavior, because of the difficulties with Thevenin and Norton equivalent circuits.

Cecil, wouldn't you rather have a meter which just indicated radiated power - everybody else does. Much more interesting. And no need to make two measurements followed by mental arithmetic. Down with SWR meters - a parameter in which nobody is interested. The very name should be investigated by local authority Trading Standards officers.

Source record: 175844

I have purchased an Alinco DX70 TH HF radio and would like to use it in a base configuration. I am leaning towards an all band vertical antenna due to space considerations and am a little confused as to what to use. I would like to cover 10 meters thru 80 meters. Which antenna is best? The Hustler model says it needs radials if mounted elevated and yet I do not see them listed in the description. Also, what is a counterpoise? I see some antennas need one.

Please excuse my dumb questions. I am new to HF.

Source record: 175845

Tom,

You're mixing up calibration with response, OM. A loop doesn't respond to an E field, if it's built right.

If properly balanced (and it may also be shielded) it responds only to the magnetic field, which is -- in the far field -- 1/377 times as strong as the electric field. Since THAT is known, it is easy to a calibrate a loop antenna in terms of uV/m. (You can also calibrate a rod antenna - which does not respond appreciably to the magnetic field -- in terms of uA/m.)

Take a wideband portable receiver, tuned to a local AM BC station, with a whip antenna, under a metal building roof. Listen as reception fades away, when the nearby metal shorts out the E-field (you can hear this under lamp standards, too if they extend over a car). Then connect a loop. The signal will come back. Considering that the E-field is 377 times stronger than the H field this is a pretty good demo.

Plus, look at the loop antennas used to measure RF. They're not only balanced (one of the tests for balance is that they should NOT respond to an E-field) but shielded from E-fields. That shield is not connected to the feedline, and is cut so that it does nor even provide a path for induced currents to flow. So THAT is not the antenna. Also, taking it off doesn't reduce the signal.

Regards,

Cortland

What do you propose to replace SWR meters for the thousands
of hams who would, without them, cook their radios/be unable
to prune an antenna/waste a lot of power, adjust a gamma, etc?

It's not a perfect tool - but, all things considered, it is the best
tool within the reach and understanding level of most amateurs.

And modeling programs, texts, and on-air discussions would
seem to demonstrate that plenty of people are interested in
that parameter.

Ordinarily, I would agree but recent experience suggests caution. I just built a rotor plate for my tower and am mounting it about three rungs down from the top. Welding it in is out of the question so I'm using some homebrew clamps to secure it to the tower rungs. I used stainless bolts and nylon stop nuts on the clamps. Unfortunately, the tower rungs aren't normal to the tower legs, so I had some bind between the thrust bearing and the rotor so had to remove the plate to do some shimming.

The one bolt that I forgot to lubricated prior to assembly galled and I wound up twisting it off. I hesitate to think about having this happen on one of the hinge bolts, although one normally doesn't worry about ever talking these things apart.

Hi Don, I would look at this page
http://www.sgcworld.com/publications/stealth.htm
A "smart tuner" or weather proofed manual tuner, with 3/4" copper tubing built into a loop around your balcony might be your best solution. Another is a magnetic loop as in MFJ's 1786 (10m - 30m) or 1788 (15m - 40m). But your desire to work 40M, 10M, 6M, 2M, and .70M might rule them out. One thought is Yaesu's ATAS-100 small screwdriver, with the proper counterpoise (maybe a ground screen on the floor of your balcony, or radials cut for each band) this one antenna will cover all the bands you mentioned. Unless you have the Ft-100 or the FT-847 you would have to use one of the controller boxes available (ad in back of QST). Another idea is folded dipoles run along you balcony for the bands you want.
I personally would go with the loop-tuner combo with separate verticals or vertical dipoles built on to the inside of balcony for UHF & VHF. Also the best chances to reduce RFI to your neighbors would be to get the RF outside. For more ideas check out my site at http://www.geocities.com/n0hc/.

This certainly provides the best coupling of power into the antenna.
It does not guarantee that the antenna is resonant (and thus radiating
at peak efficiency).

I hope not, because it doesn't.

In my opinion, the proper use of a VSWR meter is to get matching "close".
A signal strength meter in the far field is then used to peak radiated
power.

I prefer to tune with and to monitor reflected power. My MFJ 989C has a cross-pointer meter which makes it easy to tune by observing the reflected power meter reading. I seldom glance at the "forward" power meter reading except to verify that the transmitter is putting out its maximum if so adjusted. I know that if I adjust the tuner for minimum reflected power, the "forward" power is maximized, and that is the condition we all seek. I don't think that I have ever looked close enough at the meter scale to see what SWR readings are involved. This is a derived reading that may be of academic interest but has little to do with how I adjust the tuner. Neatest thing since sliced bread: dual-pointer meter.

Maybe so, but I still think can be valid on some antennas like mobile's.
I've noticed pruning loading coils and testing with antennas, that the
maximum field strength is just a bit off from where the antenna is
resonant. Overall, don't think it amounts to a whole lot, but I seemed
to a see 10-20 kc difference in the max field strength point of tuning,
and the point of least least SWR. Of course in the real world I'm not
really that nit picky as even on 75m, I have 40-50 kc bandwidth 2:1/2:1
swr. Double that on 40m. Just something I noticed when making them.
Normally I wouldn't waste any time with FS measurements here at home. At
least HF stuff anyway. MK

>misinterpret me in this direction).

Then it is settled. Since BOTH fields always accompany any radiation,
the induction field respoonse of the antenna can make no difference in
sorting out noise from signals if they are in the farfield.

It is a popular but incorrect myth that loops are quieter than
antennas that have a high electric induction field response.

>Nevertheless there are 'antennas' which mainly respond to the magentic
>field component.

That's true, inside the induction field area. But even inside the
farfield distance the field response varies.

A small loop that responds more to the magnetic induction field very
near the loop (within 1/10 wl or so for a very small loop) actually
respoonds more to the electric field at a distance somewhere between
1/10wl or so out and the farfield distance.

That is even a correction factor that must be applied to small loops
when determining the electric field at small distances from the loop.

If the electric field didn't increase with distance, the loop could
not respond to EM radiation.

>> Any antenna, even the small loop antenna, has all fields. It's just

>a near field probe in german cq DL magazine last year mentioning and
>testing the H/E relation in TEM chamber simulating a plane wave.=20

I never said they were "useless". Inn the nearfield very near the
antenna small loops have a very low field impedance. It is very low,
but it isn't zero ohms.

Immediately as we move away from the antenna the field impedance
increases. It actually is higher than 377 ohms at some distances
between 1/10 and 1 wl away from the antenna.

>> While the loop has a low impedance, remember with every time-varying
>> magnetic field there is a time varying electric field. At any

You may be able then to make the CFA antenna work!!

Please descibe a system that I can build that has only a magnetic
field, and produces a time-varying field. Remember, it can have NO
electric field at any point in space.

It does in some cases if you correct for the field impedance of the
loop, which is HIGHER than the field impedance of a short dipole at
modest distances from the loop and lower than a short dipole near the
loop.

OK, we agree the shield does nothing except affect balance of the
system. We'd better agree, because that is how it works.

>For the far field it makes no differences. But if your noise source is
>using an 'electric' antenna and you are close to this antenna you will

>mainly see the electric near field component:

Right. That is what I said. I said it is the luck of the draw.

If you are in the near region of the noise source, the dominant induction field can be anything!! It can be electric or magnetic dominant.

In all likelihood, if the noise is radiated from power lines or other large long conductors, it is magnetic field dominant near the source although in every single case (unless you can tell me how to generate a time-varying magnetic field without having a time-varying electric field) both foelds will be present.

It is an absolute myth that noise is an "electric field" and that shielding a loop stops it from responding to noise. If the loop is properly balanced and constructed, shielding the loop has no effect at all on response except to add a little bit of additional loss.

In the near field, in many cases, that is true.

>If you are right and the fields are always equivalent, which probe do I

>>
>Is it the computer itself or the magentic field produced by the monitor ?

Why does it matter? Either one could produce either field in dominace close to the source and which field is greater would vary with distance and location.

With that in mind, why on earth how could anyone say a loop or an electric field probe would be quieter in random applications? It is a matter of chance which one is less responsive.

If you are that close to the noise, you can not say which one will be better without trying both.

It is an absolute myth that loops are quieter for reasonably distant noise, and it is a matter of luck if they are quieter for nearfield noise.

The only definite advantage of a loop is you can null groundwave or direct wave noise sources easier than with a vertical. Rotating the loop can place a null in the direction of a single groundwave noise source, but you can't move the null of a vertical around without using a second vertical.

>By the way there was another article about a broadband active antenna

>by Rohde und Schwarz company and have IP3 of 30 dBm and NF of 5 dB.
>The magnetic antenna's active part has similar characteristics (the NF is
>around 7 dB and IP3 maybe little bit higher

The only thing the two loops that are very close together and at right angles allows you to do is null one "line" of response cenetered on one angle. You can get the same effect by rotating one loop.

Because the null is very narrow, the S/N only improves when most of the noise is from a single stable direction. It won't do anything for distant noise, or propagated noise, that varies in direction or angle.

In order to improve S/N ratio for noises like thunderstorms and general terrestrial and galactic (where it can penetrate the ionosphere) noise sources, the null has to be very wide. That can only occur when the antenna array is spatially large.

The biggest single increase in S/N that mosty people report, when the loop isn't used to null a local noise source, is because the loop produces less signal. The receiver isn't "banged" into saturation on sharp noise pulses, and so they are not lengthened out. The AGC is also generally operated in a non-linear part of its response at low signal levels, giving the effect of more expanded dynamics. The S meter become more non-linear, and 1 dB often is a whole S unit near the bottom of the S scale.

If I look at my S meters and measure S/N at 10 dB over nine, it might look like an immeasurable difference. If I attenuate the signals to S 1, the difference on the meter (and by ear) seems larger. That's because my receivers AGC starts to fall out of range, and my S meters are about 1 or 2 dB per S unit at the low end of the scale. Virtually all amateur receivers behave this way.

You can do the same thing with an attenuator. I often, on very noisy nights, open up the selectivity and through a large attenuator in line. It has the effect of making the S/N difference large to my ears on the receivers output.

I have runs of coax that are laid out almost a mile long. They are
single shielded cables.

When I unterminate the far ends, I can't hear any signals on a
receiver that goes to -130 dBm.

If I just connect a small one foot wire to the far end, signals
appear. Even on 160 meters or the BC band.

This tells me that a mile or so of single shielded cable has less
"radiation" than a greatly mismatched antenna 1/500th of a wavelength
long.

>measurements were performed on 100 foot runs of RG-58/U vs. RG-223/U several
>years ago, and if my filing system were organized, I could quote you the
>numbers, but there was a easily measurable difference.

You may have had defective cables or connections, or something was
unbalanced and causing common mode response.

I have all my receiving amplfiers right in the house, and very very
long ruins of coax. My own 1500 watt transmitter is only 20-40 dB out
of noise floor on a long run of cable going right past my transmitting
antenna.

I've never measured a difference on repeaters, or on receiving
systems. As a matter of fact I REMOVED double and triple shielded
cable from an apartment building that was next to a 50 kW FM and 10 kW
AM transmitter, and replaced it with propely installed single shield
cable and cured the RFI problems.

How you connect the cable is much more important than the number of
shield.

>receiver input. A few feet of RG-58 running in the vicinity of some of the
>poorer computers will also produce measurable (and hearable) signals in a HF
>receiver.

My station has up to three computers running, as well as two 30
ampere switching power supplies.

I use single shield subminature cables for internal wiring to switches, receivers and phasing boxes. I use standard foil shielded CATV cable, which has basically just a foil for a shield (a very sparse thin aluminum braid allows a connection to the foil at the connectors) for the lines from the grounding panel at the entrance to the amplifier board..

Unless I have a bad connector or connection, I can not hear anything from anything in my shack. My noise floor doesn't even move the S meters during the daytime.

Of course if I get a bad connection, the noise from the switching supplies and computer is well over S-9.

I also tie-wrapped two poorly shielded RG-8 type cables together for about 20 or 30 feet some months ago, and applied a few thousand watts to one of the cables feeding a dummy load. The cross-talk between those very cheap cables was more than 80 or 100 dB down at HF.

I have to agree with Roy. Unless you have a very very well shielded receiver and strong external fields you'll never see the difference as long as the cables are properly installed.

I remember the pains I went through to get double shielded coax for repeaters in the 60's because the books told me I needed it. What I learned later was it made no difference at all in signal at the receiver from the transmitter. The cavities leaked far more signal through than ever came from the cable, even with the transmitter and receiver cable routed in parallel for a wavelength or so.

Source record: 175789

Hi,

A couple of simple questions:

If you put an antenna on the side of large hill what is the effect on the far field pattern of the antenna ?

How big (in wavelengths) does the hill need to be in order to effect the pattern ?

An example:

The antenna is a simple dipole 30 feet up in the air. The antenna is cut to a half wave at 20 meters. The hill slopes about 6 degrees (10 foot drop for 100 foot run). The antenna is at least 800 feet from the "edge" of the hill in any direction.

Can you simply take the standard text book dipole pattern and tip it 6 degrees to get the pattern of this antenna ?

Thanks!

Bob

For a fixed or home station (most old grumpy HF operators cringe when
they hear it called a "base station", because that came from CB) the
best antenna is one that uses radials assuming you install a good
radial system.

No-ground or small counterpoise antennas, while they look good in ads,
will be very poor performers on the lower bands. Up closer to ten
meters, where the small counterpoises become electrically larger, many
of the "no ground" verticals work quite well.

Remember that any vertical antenna mounted near earth (in terms of the
wavelength), like say 1/8 wl or less above earth, needs a large
radiual system with many radials to be really effective. But if you do
install the radials, that antenna will be much more effective than a
no-radial vertical.

Tom,
Any antenna will benifit from a good ground system under
it, not just verticals. Most of us who use the lower HF
bands probably don't have the antenna at a 1/4 wave above
ground, much less higher, and antennas like these will also
benifit from a 'better' ground under it.

Bob,
Until the 'slant' of the antenna is about 25-35* relative
to ground, the radiation pattern doesn't change all that
much. There is some 'slewing', but I doubt if you'd ever
be able to tell it. At somewhere around 25-35* the pattern
starts to be directional.

Source record: 175794

Hi Tom,

there seem to be two points involved. As all of us do agree there is no time dependent H without a time dependent E.
I made some numerical simulations using a mininec based program.
I modelled a short dipole and a 2 x 2 square metres loop. The loop is shortened and I use the current in one segment as a measure for the coupling.
Two configs were checked.

#1 loop is at 'same height' as feeding point of dipole so that whole config is symmetric
#2 loop is offset by 5 metres to one end of dipole.

the loop and the dipole form one plane in both configs.

config 1:
distance current H E
10 0.05 9.5 6.1
6 0.11 7.5 8.6
4 0.2 5.5 9.8
2 0.52 2.9 10.88

config 2:
10 0.31 18.6 10.73
8 0.43 19 14.4
6 0.64 18.2 19.3
4 1.1 15 25.6
2 2.64 9 32

I think one can see from the data:
1. The current neither represents the electric nor the magnetic field alone although it's closer to the electric field
2. while both fields are necessary they are not equivalent
3. The magnetic field behaves totally different from what I expected (?)

It seems that a real world, non infinitesimal loop shows a response to both fields. The current distribution on ths loop is far from homogenous due to the presense of the (inhomoegenous) electric field.

I don't know what would change with a tuned loop and who a short electrical antenna would behave.

Seems the response of the magloop is a mixture of magnetic and electric field.

>I would like to cover 10 meters thru 80 meters.<

As a happy DX-70 owner, I hope you have as much fun with yours! I'm not sure there is any one good antenna that will "do it all" over the range of that radio. Many people find a G5RV and a small tuner the cheapest and most effective solution "for openers". Might not want to spend a lot of money until you discover where your real preferences lay! Then, you can specialize your antenna system and get performance only on the bands where you really want it.

Chip,

Your changing thread titles reminds me of my wife's two year old grandson. When he doesn't get his way, he pouts and does whatever else he can to be disruptive.

This is as bad as "this thread is closed." I really do believe that your sole purpose for participating in this newsgroup is to be disruptive.

Take a look at the GAP antennas....

www.gapantenna.com

Okay, I must confess that I'm not a GAP user just yet. Indeed, right now I'm pretty happy with my 1/4 wave, 20m ground plane mounted on the roof (up 28 ft.) with four radials. (By the way, the higher up the base of the antenna, the fewer radials needed.)

However, I've been doing some research on multiband verticals and find the GAP very different and interesting. I'd love to hear from others with their thoughts.

Yes indeed Ralf, it is always a mixture at any distance in any
antenna we can build!

The shield doesn't change that at all, except as it changes balance of
antenna.

So now you see the truth under the popular myth. We don't know the
field impedance of the noise, we most likely have no idea what it is
unless it is the far field, and in that case it would make no
difference what antenna we used. Only a response null in the direction
of the noise compared to the response to the desired signal would
reduce the noise.

A magnetic loop isn't "magnetic only", it can't possibly be if it
actually couples to space,

As we move out from the antenna, the field impedance changes. It might be low at the antenna but in a small distance it is actually higher than far field , and with a small dipole voltage probe the opposite occurs!

All the people saying closed loops are quieter because they are "magnetic" loops are just "repeating things" that they hear, and those things are not correct.

So what this means is you just have to try an antenna an see if it helps. If the noise is induction field coupled, certainly the "mode" of the antenna can make a difference. The actual effect that makes an antenna quieter in most cases is simply the directivity, unless the noise is being generated in or very near the antenna. And if the noise is being created in or very near the antenna, we really don't know whether a loop or a probe will be quieter until we try it.

And the shield does little except change balance.

Neat, isn't it? This loop-thing has to be one of the most entrenched myths circulating.

Better yet, take a listen to them on the lower bands....if you can
hear them in the background noise.

They work OK on some higher bands, but they really stink on the lower
bands. A modest mobile antenna can actually be better on the low
bands.

many thanks to Jim, Dale and Martin for their suggestions. i'm not married to that balun, mostly
it represented a convenient, weatherproof center insulator. think i'll rig up a couple of capacitance
hats today and see what happens, otherwise install a plain center insulator and remove the balun.

trying to avoid a 15 meter trap cause eventually i planned to add 40 meter coax traps and additional
wire to the ends for 80. thought 2 traps per leg would cause too much sag.

btw, rig is ten tec triton iv. now the days when i would tune my dx100 into a light bulb, and didn't
know (or care) what the swr was, look nice and uncomplicated...

About once a month I post the availability of this font that I had
modified by a commercial font designer. It is a true slashed-zero Andale
Mono fixed-width font extremely suitable for DXBase 2000 / 2001 and really
any logging software. It's advantages are two-fold

1. It allows for easy discernment between O's and 0's with the slashed zero

2. Because it is a fixed width font it provides perfectly aligned columns in
the DX cluster windows.

Available as a 47K zip file download with installation instructions.
Last month there were over 230 downloads of this font.
It is on the Software Download Page of my site directly beneath the text
that describes DXBase 2001. Enjoy.....it's FREE.

It seems somewhat obvious to me that a far-ranging ground slope,
extending far into the far-field, would lower the take-off angle
of the maximum gain point referenced to level ground in the
direction of the down slope and raise the take-off angle in the
direction of the up slope. If the slope extends far into the far
field, it's like taking a level ground plot of the radiation
pattern and tilting the azimuth.

Yep, but an Apple computer, for instance, won't display that zero
correctly if it was typed on an IBM/Microsoft machine.

My down slope is greater than that, at least two miles, maybe more.
I'm close to the highest point in Madison County, TX. I would guess
that 10 wavelengths is enough to have some effect but that is a
qualitative opinion, not a qualitative one. I recently read something
about this effect but I can't remember where I read it.

Cecil,

That was the logic I was figuring on. However it would not be the first time I got something like that wrong working with antennas. A lot of it depends on how many wave lengths is enough. Is this something that you need 10 wavelengths for or 100 (or 1000 ....).

Ya, but...

Just because _you_ can type a slashed zero with your font, and just
because _you_ can see it's rendering on _your_ screen, means *nothing*
for the hundreds of thousands of usenet users out here.

I suppose your font is proprietary to the operating system from
from the convicted monopolist from Redmond, Washington -- nicht wahr?

Saturday, November 25 2:05 PM SGT

Strong solar storms could wreak havoc in Northern Latitudes
WASHINGTON, Nov 25 (AFP) -

Across the United States this weekend, fire alarms and anti-theft devices may be triggered for no reason, pictures on television screens may flicker and fade to black, and entire communities could be plunged into sudden darkness.
Such unusual goings-on things could result from what scientists describe as a wave of major geomagnetic storms expected to strike beginning late Saturday and last for several days.

In an alert issued Friday, the US government's Space Environment Center said "a major solar flare from a large, active sunspot group" was observed on the Sun from Boulder, Colorado, last Thursday, at 8:13 am local time (1513 GMT), likely producing "additional major events."

The solar radiation storms and strong geomagnetic storms categorized by the center as a "G3 Event", officials said.
Under such storms "power system voltage corrections may be required, false alarms triggered on some protection devices, surface charging may occur on satellite components, drag may increase on low-Earth-orbit satellites, and corrections may be needed for orientation problems," the center pointed out.

The list of possible calamities doesn't end there, however. The storm wave could cause interruptions in navigation satellite communications and become a real headache for high-frequency ham radio operators, according to the center.
"In the worst case scenario, power can be lost," Norman Cohen, a space environment forecaster with the National Oceanic and Atmospheric Administration, told AFP. He said failures of power grids were more likely to occur "at higher latitudes in both hemispheres," but the geomagnetic storms -- to continue for at least several days -- would affect the whole planet.

"It will be global event. And we won't know the magnitude until it actually starts," Cohen stressed.
He said the flare observed on the surface of the Sun on Thursday has spawned a large cloud of plasma, which is heading towards the Earth. "From its appearance, we have been able to determine that it was Earth-directed," Cohen explained. "It will be a major event." The magnitude of the storms was expected to reach six or seven on a scale of nine, according to the forecaster.

As a result, orbiting satellites may experience "some orientation problems" and "will need correction from ground control," Cohen said. That may affect some communications, but television networks and cellular phones should be working normally, said the forecaster. If interruptions were to occur, they should be brief. Power grids, however, may be worst-equipped to withstand the geomagnetic onslaught from space. In 1989, most of the power grid in the Canadian province of Quebec went down for an expended period of time due to such a storm, Cohen reminded.

On the bright side, night-time skywatchers in areas far beyond the Arctic could be treated to a spectacle they have never seen before. Aurora Borealis, otherwise known as Northern Lights, could be seen in North America as far south as the US states of Oregon and Illinois, the center said. "Most of Europe will be able to see it too," added Cohen.

He said in Illinois and Oregon, the aurora will probably be visible starting at around midnight Saturday. In Europe, it is most likely to be detected on Sunday and following days after dark.

Is there anybody out there who cannot see the slashed zero in the parenthesis above, or in the parenthesis here (ï¿½)? I was under the impression that this character was included in standard ASCII, and therefore should be visible on all computers using western character sets. Perhaps I'm wrong.

You're wrong. I see a question mark in the parenthesis when reading the
post, and backslash three three zero in writting this followup.

The default character set here is US-ASCII; I had to change it to
ISO-8859-1 to even get this thing to post.

Hi Lloyd,
I do not know the Lowrance brand however the following is true for all gps receivers.
The satellite transmissions are on 2 frequencies L1 signal at 1575.42 MHz and L2 signal at 1227.6 MHz.

All satellites transmit on the same frequencies and each satellite uses a unique orhthogonal code for its PRN (pseudo random noise) sequence. In this way the receiver can distinguish each satellite even though they are onthe same frequency (spread spectrum at its best)

The L1 signal is the CA or Coarse Acquisition code (read here civilian uses) and the L2 signal is used in P or Y code capable receivers (read here military).

encoded on each satellite transmission is the ephemeris data etc which is used to determine your position. This data is encoded at a data rate of 50 bps.

AS of a few months ago there is no selective availabilty applied to the empheris data, so now position indications are far more accurate than the +/- 100m specification for CA receivers. Some receivers used the L2 signal (even though they cannot extract the data) to give predictions on atmospheric errors.

When your out on the ocean, you have a clear view of the horizon and you are more likely to acquire satellites that are on the horizon.

There is also a russian satellite nav system called GLONASS. this operates in the bands of 1246 - 1257 MHz and 1602 - 1616 MHz.

There is also a system which integrates GPS and inmarst 3 to provide better atmposheric error prediction and correction. Dont know to much about this !

Thats enough for a start, if you have any further questions just post em.
Cheers,
Greg

> W2MDM
Ok Mike,
Gotta get my two cents worth in also.. I would as Rick has sugested that you start with something cheap if possible put up a dipole feed it with open wire line.. find an MFJ 901b tuner or similar unit to feed it with until you get the feel of the bands.. then make your Choice.. as a generl (I mean general rule) A vertical will work better on the lower bands IE 80/40/30 meters. but there are no Shortcuts.. Verticals without radials will work but not as well as with them.. that's the short answer.. You need to determine your main interest before you decide which way to go..
For 75/80 and forty meter ragchews.. a low dipole is almost always better than the vertical , but if you want to work Dx the the vertical is better on those bands (assuming you have a low noise RX antenna.)

If I had only one antenna that I could use and wanted multi band performance from a Vertical I would choose one of the Butternut models.
They have extensively tested and written their results for all to read.. (no magic Just plain proof). you can read about it at
http://www.bencher.com/pdf_download.html#vert_ant

look under Tech notes. you'll need a PDF reader such as Acrobat which if you don't already have it can be down loaded free.
There are 4 Articles you need to read.. "Dirty Little Secrets 1&2 ,Ground Radial systems and Why Radials?"

Also W4Rnl did a good paper on verticals at
http://www.cebik.com/radio.html

Remember that any wire will radiate some RF in some direction.. the Trick
is to radiate the most RF in the direction you want at the moment you want..
and in this no antenna system is perfect. all are a compromise of one sort
or other.. but there is alot of miss understanding on this issue !

Hope to hear you on the air.. Soon Mike
God Bless, happy hamming 73 Dave KC1DI

: Let us start with a transmission line (TL) of impedance 50 Ohms,
: length t (the time for one way propagation along the line) and a
: generator with an output impedance of 50 Ohms.
: Leave the right end of the TL open-circuit.
: Set the generator to 50 V (into 50 Ohms) and attach it to the left
: end of the TL.

: At time t, the voltage step reaches the end of the TL and the current
: can flow no further since the TL is open-circuit.
: But charge is still arriving so a voltage step from 50 to 100 V occurs
: which propagates back along the line.

: Now the TL is fully charged to 100 V and no current is flowing anywhere in
: the line.
: The generator is no longer adding energy to the TL.

How do you know this? Have you actually tried this experiment, and seen
the power draw by the generator go to zero?

Isn't it possible that the generator is now trying to dissipate this 50
watts of power and rapidly overheating?

:> And yet believers in reflected power would like me to accept that > there is

:> 50 W of forward power and 50 W of reflected power for a net 0.
:> But I can easily see that there is no power flowing in this TL, anywhere.
:> It is only a charged capacitor.

Here is a setup that will disprove your statement.

Generator - circulator - transmission line (open on the far end).
On the "return leg" of the circulator, attach a load resistor.

If you measure the power in the transmission line, you have 50 watts
forward and 50 watts reflected.

The load resistor will dissipate that 50 watts - proving that power
returned back along the transmission line.

If there were no reflected power, then that load resistor would not heat
up.

And don't argue that adding the circulator to the system invalidates the
experiment. It doesn't. The only way power could get to the load resistor
is if power flowed back towards the circulator from the open end of the
transmission line.

:> As for the 50 forward and reverse, one could just as easily argue that it
:> is a megawatt forward and reverse. It yields the same result.

Nope. You only measure 50 watts in each direction. So stating that there
is a megawatt in each direction is silly and meaningless.

Well, Jim, this comes from "The Radio Amateur Antenna Handbook", William Orr and Stuart Cowan (1978), pp. 92, 93. A chart on p. 93 shows that on the ground, a vertical needs 120 radials, at 0.2 wavelengths it needs 10 radials and at 0.5 wavelengths four or five will do.

And, as I said, I've been getting excellent signal reports from all over North America (my QTH is Colorado). I must admit that I have not worked any real DX , but, I don't really try. I'm just happy to ragchew on CW.

Hey Mike,
I use a 65 and 135 foot #14 insulated wires in a inverted L configuration. They both are fed at the same point and same feedline. The vertical section is 55 feet and the horizontal parts go in opposite directions. This antenna setup is matched with a homebrew T type tuner. It works very well on everything from 160 to 10. I have a little over 3000 feet of #14 insulated copper in the ground as the radial system. It is composed of 65 and 135 foot radials all connected to a 8 foot 3/4 inch copper pipe in the ground. I do have 4 of the 65 foot radials terminated to a 8 foot copper pipe also. Soil here is sand. Give it a try if you have the space.

That is not slashed zero, it is a vowel in at least Norwegian and
Danish, the uppercase ï¿½ is at U+00D8 and the lower case ï¿½ at U+00F8.

>Yep, but an Apple computer, for instance, won't display that zero
>correctly if it was typed on an IBM/Microsoft machine.

These characters are in the same positions in Unicode, ISO-8859-1 or
Latin1 (as used by most modern unixes), Windows code page 1252 etc.

MS-DOS and Apple have both their own incompatible code pages for
Western European languages. HP-UX had their own incompatible code
pages and of course all big IBM machines use EBCDIC, which is
completely incompatible with anything else.

Never expect a character typed using the Option key on a Mac to come out the same on a Windows machine. Never expect a character typed using the Alt key on a Windows machine to come out the same on a Mac.

> > I suppose your font is proprietary to the
> > operating system from from the convicted

> > -- nicht wahr?
>
>
> Nope, I have the Cupertino operating system, with a whole lot of fonts
> (some proprietary and some not).

The character in parentheses looked somewhat like a slashed zero on this Macintosh, but it really is not. It was typed by holding down both the Shift and Option keys while typing the letter "o". If a Windows user typed what looks like a slashed zero, when I looked at it on this Mac I have no idea what it would look like, but I'll bet it would look different (unless he typed an ordinary zero; then it _WOULD_ look like a slashed zero to me).

This is one reason why Mac users should never use the Option key in e-mail or newsgroup posts, and likewise Windows users should never use the Alt key. I figured out from context some time ago that the lower and upper case Pi characters I occasionally see on this newsgroup really were intended to be 1/4 and 1/2. I can get those Pi characters by using the Option key, or both the Shift and the Option keys, with the letter "p" (easy to remember) but I have no idea what they would look like to a Windows user. Let's find out: Here's the one with Option alone: ø. And here's the one with both Shift and Option: ø.

By the way, the current versions of the Monaco and Mishawaka fonts (both monospaced), and the Chicago font (not monospaced) on the Mac give a slashed zero just by typing the ordinary zero. Since I use Mishawaka as the screen font for my e-mail program (Eudora) and my newsreader (NewsWatcher) I see lots of those slashed zeros onscreen.

>sets. Perhaps I'm wrong.

Standard US-ASCII (ANSI_X3.4-1968) is that obsolete 7 bit character
encoding containing 0..9, A..Z, a..z and 24 punctuation characters
and 32 control characters. Standard US-ASCII and its international 7
versions (ISO-646, in which a few punctuation marks were replaced with
non-English vowels and consonants) were used in most non-IBM computers
into 1980's. For instance the mechanical Teletype or the VT-100
terminal supported only US-ASCII or other international 7 bit
variants.

The only way to display the (ï¿½) character on these systems is to use
a Danish or Norwegian terminal and send the 0x5C code to the terminal,
which on the US-ASCII terminal would be displayed as the backslash (\)
character.

In 1983 the VT-220 terminal supported an 8 bit with some modifications
became the ISO-8859-1 (Latin1) in 1987 supporting most Western
languages at the same time, includes the (ï¿½) character.

Thus, if you are using 7 bit devices, such as VT-100 terminals, you
will not see that character.

>> I suppose your font is proprietary to the
>> operating system from from the convicted
>> monopolist from Redmond, Washington
>> -- nicht wahr?

Western Windows variants use code page 1252, which is superset of
ISO-8859-1, so the ï¿½ is in exactly the same position.

However, in MS-DOS, the US code page 437 does not contain the ï¿½
character at all and the Western European code page 850 keeps it in a
different position, thus, some transcoding is required to display it.

The Mac Roman character set has the ï¿½ character in yet an other
position, so some transcoding is still required.

>The character in parentheses looked somewhat like a slashed zero on this
>Macintosh, but it really is not.

As far as I can figure out, there has never been any slashed zero characters in any computer character sets. However, there has been a large number of font variations that displayed the ordinary digit zero in somewhat different ways. Some used a completely round glyph, other used an elongated glyph, some a truly elliptical glyph, some a zero with a right facing slash, some with a left facing slash, some used a centre dot and some even some kind of underscore to distinguish from the letter O. All these are simply glyph variations of the ordinary zero digit.

On hard copy devices you could use overprint by sending the digit 0, backspace and slash. In Unicode a slashed zero could even be constructed by using U+0030 U+0336 (digit zero and combining long stroke overlay).

All the talks about slashed zero appearing in all fonts is a misunderstanding, by people who think that Norwegian and Danish uppercase vowel (ï¿½) U+00D8 and lover case vowel (ï¿½) U+00F8 look like a slashed zero. I am writing this on a Norwegian keyboard layout and that vowel is immediately to the right of the L-key. This paragraph should be correctly displayed on any system supporting ISO-8859-1 (Latin1).

Yes, but it's *not* a zero...it's <Option><Shift><o> Hex 'AF' which
may not display the same in other fonts or operating systems. As far
as I know, codes above 127 are not part of the ASCII standard, which
is 7-bit, and they will vary from implentation to implementaion.

An ascii zero is 30 hex. Other codes will display what looks like a slashed zero on some machines. Software, such as logging programs and call sign capture functions in terminal programs, are not likely to recognize these other characters as a zero. Sending anything other than 30 hex should be avoided. If you want to see a slashed zero, the correct way to do it is to install a font that displays a slashed zero on the screen for 30 hex.

That's a very strange comment coming form an individual who is
widely recognized as the single most obnoxious abuser on this newsgroup,
not to mention the mail lists and interest groups, such as Antennex, that
you have been tossed out of. The rest of us are all still on those
groups, unhindered by anyone who would seek to intrude and disrupt or
bring to a halt any and all discussion on certain subjects, such as you
did on AntenneX after openly announcing your intentions on the NEC
mail list.

How does it feel to be the sole possessor of that recognition?
Your legacy began all the way back at the Arecibo Observatory, where you
were almost sent back home for spamming the observatory's email system.
A real harbinger of things to come.

This has gone on long enough.

Under guidance from my attorney, you will be receiving a cease and desist order for the malicious and prevaricative libel which you continue to attack me with, indeed, repeat even here in the attached post . Continued attacks from you will lead to a suit for malicious libel against you.

Mr. Trask continues these attacks for no other reason than obsessed and focused intent to defame my reputation and tarnish my ability to practice and make progress in my profession.

Nathan Cohen, Ph.D.

It is quite clear that AOL does not take its terms of service seriously at all.
The fact that he has been allowed to disrupt this newsgroup for weeks now
reposting messages. changing the thread names to the names of the original
poster is clear evidence that AOL gives it lip service, not real service.

Paul,

I would find it helpful if you posted the list. I am always interested in antenna books to add to our library.

I get so much e-mail from hams that much of it gets filtered out; better to put on this NG.

Best of luck selling the collection, and I hope I can help on this:-)

Thanks!

The situation is that I publicly requested the cessation of my listing as a 'thread topic'. Being archived in such a manner is a focussed intent to libel me and thwart my professional and personal efforts, and damage my reputation. The evidence for this--and the damage--is extant and easily proven in a court of law.

Listing me as a 'thread topic' led to an incredible series of prevarications and fabrications with the sole imtent of libeling me. That I HAVE been libeled is my position and that of my attorney.

Those who continue to invoke me in this context are libeling me with malicious intent. My person is NOT a subject of the rec.radio.amateur.antenna NG and my public request for cessation must be honored.

I am not a public figure; the abuse goes on whether I post or not (that is, without ANY provocation from me whatsoever); and I will NO LONGER tolerate ANY abuse from anyone here or elsewhere.

Speculation has been introduced that I am operating under the direction of counsel. I will confirm this.

Now stop talking about ME and discuss antennas.

Thank you for your assistance.

Nathan Cohen, Ph.D.

Message-ID: <jobU5.2269$LQ3.3245@newsfeed.slurp.net>
Source record: 175725

.. interpret deja's database (archive) reports:

Greetings!

Thank you for contacting Customer Support.

Deja.com uses a feature within the database search referred to as the "lazy eval" search. This type of search will pull up an estimated number of hits in a shorter amount of time than the same search for an exact number of hits. You would still receive the same number of hits, regardless as to whether an exact search was conducted or a lazy eval search, but with lazy eval, the hit list was being reported in larger ESTIMATED hits in order to quicken the search time.

As you continue your search through the given hitlists, the approximation will become more accurate, and at times will completely end-though it still indicates that there are still an estimated number of articles left.

Choosing a higher number of hits per page (50 or 100) will give you a more accurate list from the start- though you must scroll through further to get the exact number.

We apologize for any confusion or inconvenience this may cause.

In addition, be aware that search results by author are often skewed by crossposting. Also, a general search using your handle will include results which merely contain that handle, such as a reply to one of your posts. The easiest way to find your postings is to go to the power search page (http://www.deja.com/home_ps.shtml) and type your full posting email address (cloacus_maximus@manurespreader.com) in the "Author" field. This will bring up a more
specific listing of your posting history.

If you have any further comments or questions, please don't hesitate to contact us at your convenience.

Deja.com, Inc.

i was fortunate to be looking when the blast went at around 1600 yesterday.....
there were two reversed treble clefts in the southern area of 9236? that
blueshifted more intensly than any i had seen prior. simultaneously a vertical
and horizontal prominence formation appeared and went away in about 15 min.

3121. DK3 Screwdriver UNUN?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-26 00:00:00 UTC
From: "William R. Moore" <wr.moore@worldnet.att.net>
Message-ID: <ObcU5.6451$FT.380569@bgtnsc04-news.ops.worldnet.att.net>
Source record: 175727

I have obtained a DK3 screwdriver that has never been used. I am constructing the UnUn matching transformer that is specified in Johnson's notes. I have 2 questions.

The notes (Figure 10) call out the number of turns explicitly only once and that number is unreadable on my copy. The diagrams look like there should be 14 turns. Is that correct?

In winding the bifilar turns, should the wires be twisted or wound in parallel?

Tnx es 73,

>I know they are aware of the situation.

They may be aware of the situation, but if history is any guide, they will not take an y action. AOL allowed disruptive behavior to continue for years on the Ham Radio discussion board, with the net effect that there are now only a handful of posts per week. Most reasonable people decided that the board was a complete waste of time.

What I see is an equal sign ("=") with a vertical bar ("|").
It be one of the "IBM Graphical Characters" for drawing boxes: x'D8'.

>I was under the
>impression that this character was included in standard ASCII,

Standard ASCII !!! LOL !! At best ASCII is 'standard' up through
x'7F' -- and is wide open for (re)intrepretation from x'80' - x'FF'.

First of all, I don't want to swap Cecil. I, at least, want to buy. Second of all, I am interested in antennas, so such a list would make sense HERE to myself and many others.

Perhaps a cross listing might be useful though.

Source record: 175734

Hi Randy,

IMHO the UNUNs that go with many of the screwdrivers don't work very well, especially on bands such as 10 meters. If you have this problem, you might just want to wind a coil and parallel it with the bottom of the antenna (feedpoint). Find resonance on 75 meters, and it will work (usually) on all bands. I have run into one or two that had to be tapped in 2 places, in which case one can use a simple relay to switch between the two.

According to the news headers, you are using linux and slrn and your character set is declared as iso-8859-1 and the original message also contained an explicit code page declaration of 8859-1. How on earth did you manage to display the original text in MS-DOS (OEM) US code page 437 :-). There is definitely some problems with your configuration.

I know I shouldn't do this but here goes. Frankly Ed part of the problem on the AOL message boards can be pointed to you, and you very well know this fact. You consistently baited the various trolls on and on in a sort of tit for tat game. Quite frankly I was quite relieved when you got your panties in a twist and left the message board. Do you know why? Because like a lid on the air if you ignore them they GO AWAY. When you stopped replying so did the resident lid. I see you have substituted your AOL hobby for this NG well, so be it. But do not feign innocence in this whole debacle.
Your manner in which you operate is much like a person who screams their house is on fire and instead of putting out the fire they yell some more allowing the flames to consume the house.
Here is a hint if you do not agree with someone and it breaks down to personnel attacks IGNORE them. This may take more self control than you have demonstrated but do try. Perhaps the use of filters on the NG may help, I am sure you can manage to operate them.

Once again for you to act innocence is quite funny. It may fool a few on this NG but I had an eyeful of your mode of operation. So peddle that junk elsewhere.

Well keep throwing kerosene on the fire Ed.

Modification to 6 meters should be no problem. Modification should consist
of
shortening each of the elements and then adjusting the distance between
them.
Most antenna books will have the correct dimensions for everything. The
moonraker
is a great source of parts for creating what ever you want.

You may, however ,want to hold on to it for a while, without modification. I
heard that the Moonraker 4 is being discontinued and, in a little while,
they
might be worth something.

Bill--

Please tell me how you can be so sure. I seem to recall buying over a dozen items from people who are on this NG. These include:

slotted line; antenna books; smith charts; terminating resistor; antennas; impedance bridge; and others.

So, what is it in my history that allows you to make such an inaccurate and factually unjustified assertion as the above?

You'll need an antenna about 2 Km up above sea level to
"look over" the curve of the earth at a station 250 Km away, for
reliable reception. Actually, the combined height of thje transmitting
and the receiving antennas comes into play - 1 Km high at each
end should do it. And - that assumes no intervening mountain
ranges - the two antennas must be able to "see" each other.
A high gain antenna cannot make up for the height problem, but
would be needed in any case to compensate for path attenuation.

One of the things wrong with this newsgroup is people not following the guidelines. The ad hominem attacks upon you are also against the guidelines. Guideline violators decrease the usefulness of the newsgroup for everybody, including themselves.

For the record: Chip and I were friends before we encountered each other on this newsgroup and this is a simple disagreement between friends.

This makes me curious. In the US, is it legal to operate a CB that has been converted to 10 meter Ham operation, assuming of course you are a legally licensed ham with privileges on 10m? I'm not sure how this would be different from building your own radio from scratch, which is legal.

If it is illegal, I'm wondering how other countries view this kind of thing.

Just curious,

Robert / KG4FGN

Never say never. Almost all of the older home PCs had the slashed zero. My trs-80 does. I just fired up my Commodore 64 and my 128, both of them have the zero slashed (heck they even have the zero slashed on the keyboard).

A slashed zero font with it really being the zero and not a special character is a cool addition. Being Monospace helps, there aren't that many monospace character sets out there that are easy to read.

Chip- simple- from your own past postings, we have been assured that you know when people like Dr. Kraus, Dr. Best, Dr. Maxwell, and other very knowledgeable people are in error. You have told the whole world this. You can only adopt this position if you 'know it all'. I therefore fail to see your need for these, or any other, books. I doubt that there is a single book on the list that even recognizes that Nathan Cohen, PhD even exists. You have set up this background, you will live with it, maybe even in court. (your choice).

I REALLY hope this helps.-Bill-W4BSG

> Almost all of the older home PCs had the slashed zero.

Many early PCs displayed the ASCII zero with a slash on the screen.
The ASCII character however was 30 hex, the same character that
displays a non-slashed zero on most fonts. 30 hex is and always has
been the *only* valid ASCII code for zero. It is up to the receiving
terminal design to determine if the displayed zero character has a
slash or not. Any other character will fail in software analysis even
though it may "look" like a zero on the screen. The only proper way to
display a slashed zero is to have the receiving machine display a
special slashed zero font in response to receiving a 30 hex or to have
the receiving software send a slash zero "look alike" to the screen in
response to receiving a 30 hex.

Hello--
Also, IIRC many of the late-1970s-vintage "dumb terminals" (e.g., Televideo 910, ADM xx, etc.) either included a permanent slashed zero in their character-display ROMs or had a switchable option to display either a slashed zero (or one with a dot in the center?). Can anyone confirm this?

73--

Well for what it's worth I have an EDX-2 tuner that I use with my DX-70T. I had it out on my 10 AC in central Oregon.....(high desert) with 6 radials underneath it tied to the pipe it was mounted on. I had 50 ft of random wire connected to the EDX-2......it worked very well. I had 3 thunder cells pass with 6 or 7 miles of me.......no problems. As near as I can tell when the power is removed from the tuner a relay brings the antenna to ground.......... Just my observations.

I don't want to be a pessimist, but I'm afraid that they will be pretty
large plans (ie, large antenna!). Reliable reception of FM radio
frequencies at that sort of distance will be really difficult, even with
a large, high-gain antenna. Even if you do put up an antenna of
fantastic gain, the problem is that you are likely to pull in all the
stations 'down the beam' of the antenna, to a distance of over 2000
miles. I don't think that there is a satisfactory solution.

Ian.

I demonstrated a gaping hole in your logic with no need
to consider your criteria. As you mentioned: "Only a single
counter-example is needed to disprove an hypothesis." Your
hypothesis is that there is no such thing as reflected power.
TDR disproves it.

Apparently, you have not used TDR, so I'll explain:
TDR = Time Domain Reflectrometry. You place a single
pulse on a transmission line. You observe the pulse at the
point that the pulse generator is connected to the line, using
an oscilloscope. When the line is terminated in its characteristic
impedance, you scope displays a single pulse. Open the line
at the far end, and your scope displays the initial pulse and
the reflected pulse. The time between pulses can be used to
compute velocity factor or electrical length or physical length,
depending on what factors are already known. The technique
is used to diagnose where a fault is (physically) in a line.

TDR demonstrates, beyond argument, that power on a line can be
reflected by a mismatch. Any mathematical, logical or empirical
agruments to the contrary must therefore be flawed. QED

Ok.
First, take your TV to a friend's house, where his TV receives
UHF ok. Test it there on his antenna to ensure your TV receives
UHF ok there.

Next: do your nearby (within 1 mile) neighbors receive UHF ok?
If not, you may not be in range of a UHF station.

If your TV is ok, and if your neighbors receive UHF ok,
then either your connections are wrong (at either the antenna
or the tvf, or both) or your downlead "system" is bad.
By "system" I mean cable, connectors, splitters etc.

There is nothing else possible. If your tv works properly,
and if your nearby neighbors TVs receive UHF, I would
say it is time for you to get a professional in there.

I once heard Collins Radio's chief antenna engineer make the remark that
"reflected power is just a mathematical convenience."

Never quite knew what to make of that, since "something" other than a
"convenience" is moving the reflected power meter needle. <:}

He wasn't there all that long . . .

To put too fine a point on it, TDR demonstrates that measurable
reflections take place on a transmission line. We measure these,
usually, as voltages. It remains to demonstrate that reflected voltage
"signals" convey "power."

Source record: 175701

The manual "talks" dimension A and dimension B.

Dimension A is the length that the topmost tube sticks out of the next tube down which in turn attaches to the top of the matching coil.

Dimension B is the distance from the bottom of the matching coil body to the very top of the bracket that holds the first set of decoupling radials.

The dimensions come from charts with one exception. They explicitly specify the dimensions for 146 Mhz. Dim. A = 22.5" and Dim. B = 32".

For other frequencies, you can figure it out from the table below. The change appears to be very linear.

Dim. A Dim. B
140 Mhz 25" 34.5"
145 Mhz 23" 32.5"
150 Mhz 21" 30.5"

If you remember, the very top of the bottom radial bracket is supposed to be even with the very bottom of the tips of the upper radials.

Mine has lived through many, many years of Colorado weather. The wind gets very severe here with over 100 MPH gusts being routine, and occasional 130+ gusts. The antenna bows, but never permanently deforms. It survived a lightning strike back in June too.

Good luck.....

My 1989 Rohn catalog does not specify what size the hinge bolts are.
The fold over section is listed as a HS25FO Hinge section with bolts
and nuts. The boom section has six 5/16 x 1" bolts and two 3/8 x 4"
bolts at the "A" clamp. The larger tower section bolts are grade 5,
5/16 x 1 1/2" NF bolts. The larger bolts on the 45 G are grade 5,
7/16 x 2 1/2 NC bolts.

I don't know if this has been discussed but how about a diversity receiver configuration with two antennas and two receivers and some logic circuitry to switch the audio. Perhaps the stereo subcarrier- blend circuitry could be used to detect a fade and direct the diversity logic. Of course I am assuming that co-channel interference is not an issue,

From: Robert Parker <rparker@sprint.ca>
Message-ID: <vyGU5.5166$HA4.92584@newscontent-01.sprint.ca>
Source record: 175575

Get a set of TV rabbit ears. Connect 50 ohm coax. Hotizontally extend the antennas in a dipole fashion. Adjust both sides equally at the desired frequency of operation until a low SWR is found. You can mark there positions so you can quickly move from 2m to 70cm. Work great as a backpacking antenna or home. Total cost of antenna $1-$2 for a use pair of ears.

Afraid thats not true. There is no difference how you feed it, tuner or no tuner. The antenna can't tell the difference. All it sees is rf. How it got there, it couldn't care. The reason some of these antennas burn up with a tuner is with the tuner inline you are getting full power out of the radio. This extra output is what smokes the cheap antennas, not the tuner. If you ran the same higher power from a rig that didn't need the tuner, it would smoke the antenna also if the antenna was low duty rated. The best thing to do is get an antenna that can handle power. I'm not crazy about GAP's as they use a piece of coax as a resister to increase bandwidth. Thats like hooking a dummy load in with your antenna to share the rf. Myself, my vote is as most the others. I'd go the butternut with radials. Or better yet, make it yourself. Thats what I do. They want too much cashflow for the common vertical antennas on the market. MK

This is a not-so-stupid question I have often idly pondered myself. My reasoning is as follows. An antenna placed in an electric field and terminated so that it extracts power from the field would be expected to make that field non-uniform, more so in the close vicinity of the antenna. If this happens over a volume much larger than that physically taken up by the antenna then power is being "stolen" from other areas in the field and the neighbour gets less signal.
Using the reciprocity theorem for antennas: just as a transmitting antenna creates an electrical field strength over a volume of space, I can't see why an identical terminated receiving antenna shouldn't reduce the field strength of any external incident wave in the same way over a similar volume.
Anyone wanna comment (or is this just obvious and I don't need to devote my last few grey cells to it)?

David

Correct, in order to get some analytic expressions I assumed a infinitesimal electrical dipole and calculated the field. All is based on what is called a vector potential A proportional J/(4 pi r)*exp(ikr), where A and J are vectors. The H field is proportional to rot H, meaning basically a single derivative of A with respect to space, meaning a linear combination of a 1/r and a 1/r^2 term. The E field is proportional to rot (rot A) meaning something like a double derivative of A with respect to space meaning a lnear combination of a 1/r^3, two 1/r^2 and a 1/r term. For large distances the 1/r^3 and 1/r^2 terms go to zero and only the 1/r term survives (this is actually the far field). So you see that both expressions are equivalent in this case.

Close to the antenna the leading term is the 1/r^3 term for E and the 1/r^2 for H meaning there is always a distance where the E term is larger than the H term (I think these things were mixed in one of my earlier postings).

> actually couples to space,

Correct, dH/dt always means dE/dt. Anyway I continued to make some simulations using NEC2d at the weekend, since the magnetic field distribution I reported on Friday looked strange to me. I calculated the near fields of a short dipole (20 mtrs long) at 1 MHz at points at distances between 3 mtrs and 100 mtrs away from the antenna. For d = 80 mtrs and plus I observed a transition to the 1/r bahaviour as expected. Scaled to same far field value the E rises faster than the H (on a double log plot). In opposition to my FRiday posting a believe the values obtained with NEC2d, since they look very close to what I obtained in a homework in my lecture course on electrodynamics. I don't konw if I chose a segmentation which was not fine enough on Friday or if the integration routine of the MININEC based program has an error.

In a next step I calculated the response of a magentic and elctric antenna to this field. The configs were similar to those I reported on Friday. The response of the magnetic antenna was defined as the current on one segment (always the same of course), the response of the short electric antenna was defined by assuming the antenna terminated by a 1 MOhm resistor and measuring the voltage across this resistor (modelling an active antenna, because this is what I was interested in actually). Two different magloops were taken, both with a square geometrical shape: One has 50 cm side length, the other 2 mtrs.

In a config close to config 1 from Friday I obtained:
1. For a distance of 10 mtrs the S/N of both loops exceeds the S/N on the electric antenna by 12.9 dB which the tendency of slightly increasing for even smaller distances.

2. The 50 cm loop is a _perfect_ detector for the magnetic field component at all distances checked.

3. The 2 mtr loop is almost perfect as a H detector but does not work properly 3 mtrs away from the tx antenna.

Config 2 is as follows:
all antenna wires are in one plane, the probes are shifted by 10 mtrs away from the symmetry plane of the tx antenna.

1. The 2 mtrs loop is still almost perfect for the H field (I did not model the 50 cm loop.

2. By moving the probes away from the tx antenna axis I could change from a 14 dB better S/N on the electric probe to a 13 dB better on the magnetic probe.

3. By turning the probes I could change a lot.

The last two points confirm what you were saying although the do not confirm the equivalence of H and E field (wihich they can't as I showed before).

> All the people saying closed loops are quieter because they are
> "magnetic" loops are just "repeating things" that they hear, and those
> things are not correct.

Actually I do not remember if I said 'they are quieter' or if 'they might be quieter', anyway I did not repeat any myth here.
My argumentation was based on the different behaviour of E and H close to antenna and this is accepted since the times of H. Hertz (although this alone does not make it through). Anything written here follows from assuming Maxwell as 'first priciples' and using vector anylysis plus superposition principles. I admid that just looking on the magnitude of fields oversimplifiees the things (this is actually the mistake I made), since the different terms from above have different directions.

I pointed out before that I do not think that E is bad and H is good.

> If the noise is induction field coupled, certainly the "mode"

> noise is being generated in or very near the antenna. And if the noise
> is being created in or very near the antenna, we really don't know
> whether a loop or a probe will be quieter until we try it.

I described a configuration above were both antennas have there main lobe directing to the tx antenna and the loop is better by 14 dB and plus for distances of ten mtrs and less.

> Neat, isn't it? This loop-thing has to be one of the most entrenched
> myths circulating.
>
I do not believe in myhts, I believe in physics. I admid that it would have been better to put the numbers into NEC2d earlier. But there are people around in the U.S. who discuss result before they have the numbers, too (sorry, Florida) ;-)

I'm going to put a little article on my simulation on my webpage. I started to write a summary already and I can send it to anyone interested by e-mail (sorry no Winword, only PS or PDF possible); since my main attention is on my Ph. D. thesis which nothing to do with this kind of stuff this could take a few days.

Thanks for discussion anyway, seems that even 'exact science' offers enough room for interpretation

Isn't the near field proportional to square root(power) ?

Assuming a 'perfect' field strength meter and all near field coming from
the antenna, It does not matter if you use near or far field as long as
you do not change anything else.

Phil,

Some logging software gives you that information as you enter the call
prefix of the station you are working, or the DX spot you want to work.
DX4WIN, for example, lists the direction and distance to the remote station,
and also includes a 'globe view" of the short- and long-path routes from
your QTH to the other station.

<Standard Disclaimer: no ties to DX4Win, just a happy customer>

Hi Corry,

I use a Smartuner. Until now I did not find an antenna that it could not
tune, althogh sometimes things 'depend on history':
If I want to tune on band A, it sometimes makes a difference if I just
worked on band B or band C.

The large coils in the smartuner are toroids, I estimate the Q not higher
than 300 (probably less?). Putting this in to a network analysis program I
could find situations where you can loose 90 percent of your power.

If you want it to tune a mobile on the low bands it is best to put as much
L as possible into the whip instead of using the Smartuner's internal L.

At the moment I use a 20 mtr peice of wire 4 metres up and have no
efficiency problems. Worked ZL on 30 with 8 watts, Cambuchea and Viet Nam
on 20 (pile up, 8 watts) etc. Whole Europe with 2 watts on 40 is no
problem (all from northern germany). 80 mtrs could be better (I think
it's the height of the antenna)
while 160 mtrs is a dummy load (mainly to the height?).

I decided to buy the Smartuner because it is 'brand independent', so that
I don't have to buy another tuner when changing from Yaesu to something
else.

Hope that helps

Hi all,

a friend of minr lost a remote controlled model airplane a few weeks ago. The frequency he used for the remote control is close to 35 MHz. Because all electrical circuitry was working he asked me to find out, what might be the reason, IE if there was any interference possible. Apart from the 3 rd harmonic of Radio Jordan I found some american accent radio traffic between 35 and 42 MHz. Since it sounded like american CB stations here in europe (you hear tens of stations at a time), I was not able to find out what it was. Could anyone tell me what kind of service allocated there ?

> To the right of this step, the voltage is 100 V and no current is flowing;
> while to the left of the step, the voltage is still 50 V and 1 A is still
> flowing.

Actually, the total voltage at the open-circuit is 100 V which is comprised
of a forward traveling voltage of 50 V and a rearward traveling voltage of
50 V. The rearward traveling voltage is 50 V not 100 V. There is a forward
traveling current of 1 A and a rearward traveling current of 1 A. The

rearward traveling power is therefore 50 W. The forward traveling power is 50 W. The 100 V that you discuss is not a "traveling voltage", it is a total voltage comprised of two traveling voltages - one in the forward direction and one in the rearward direction. The same thing occurs with current. The zero current you discuss is not a traveling current, it is a total or net current comprised of two traveling currents- one in the forward direction and one in the rearward direction.

>

You are confusing delivered or net power with forward and rearward traveling power. If the generator is still energized with a source voltage of 100 V, then it is still supplying energy to the line in the form of a forward traveling wave. At the same time, there is a rearward traveling wave with the same amount of energy. The net energy flow or delivery to the line is zero. These concepts would be more evident if we were discussing a transmission line with loss. In this case we would also see how real reflected power is.

> And yet believers in reflected power would like me to accept that there is
> 50 W of forward power and 50 W of reflected power for a net 0.

> can easily be shown to be false by substituting Norton for Thevenin or
vice
> versa.

To understand what happens with the Thevenin generator we need to perform all of the analysis in terms of voltage and current. Doing so, we will see exactly what happens with the "reflected power". Trying to analyze or discuss wave behavior, wave travel, wave reflection, wave cancellation, etc, with power is invalid and does not yield a correct understanding of the transmission line problem.

Consider your Thevenin circuit example. At time T=0, the generator sees a total impedance of 100 ohms and delivers 50 V to the internal source impedance and 50 V to the transmission line as a forward traveling voltage. At time T=2t, the generator voltage is still 100 V and it still delivers 50 V to the internal source impedance and to the transmission line. However, at time T=2t there is now a rearward traveling reflected voltage of 50 V arriving back at the line input. At the line input, the total voltage is equal to 100 V. The rearward traveling reflected voltage of 50 V is also delivered across the internal impedance. Since it is traveling in the opposite direction of the source voltage, the total voltage developed across the internal impedance is equal to 0 V (50 - 50). Draw the Thevenin circuit and all of the voltage polarities and this becomes obvious. As a result, there is no internal power dissipation occurring in the generator and no net power delivery to the transmission line. Yet, there is real power flow (really voltage and current) in the transmission line. The fact that the reflected power (voltage and current) is real and does exist is what causes all of this to happen. If the transmission line were infinitely long and the reflections never returned to the generator, the internal power dissipation across the source impedance would always be 50 W. It is only the presence of the reflections arriving back at the generator that causes the internal power dissipation to become 0 W.

It makes exactly the same sence as non-zero frequnency so long as the
correct relationships for voltage and current are established everywhere in
the system.

> therefore not a power.
>

Again there is a confusion between traveling power and net or delivered
power. There is energy flowing across these points in the form of a forward
traveling wave and a rearward traveling wave. The net energy flow or
delivery is zero because two waves with real energy exist - one traveling in
the forward direction and one traveling in the rearward direction.

As a matter of course, I use a balun on all my center fed antennas.
Like you, it is mostly a convenient weather proof center insulator.
However, I haven't had a balun cause me any problems.

> trying to avoid a 15 meter trap cause eventually i planned
> to add 40 meter coax traps and additional wire to the ends
> for 80. thought 2 traps per leg would cause too much sag.
>

I use coax traps wound on PVC couplings and find that they
are very light. They don't add very much to the sag. My
antenna has 3 traps per leg with no sag problem, but then
I also have a center support.

I limited my antenna to 40, 20, 15, and 10 Meters due to
bandwidth problems on 80 Meters. The 80 Meter band is kind
of wide and trap antennas tend to be a little narrow banded.
If you have a small section of 80 Meters in mind for operation,
then there isn't much of a problem. As a guess, I would think
you will only get about 100 KHz of bandwidth.

When you work with traps, you will need some test equipment.
A Grid Dip Meter seems to be almost essential. The trap should
be adjusted for resonance before installing in the antenna.
Once the trap is installed, you can not get a good reading
on it any more. And, due to the shortening effect of the traps,
it is a good idea to have a antenna analyzer to find out where
the resonances have moved to. After that, adjustment is pretty
simple.

At one time I used an end fed wire that was about 96 feet
long with 5 or 6 burried radials. It operated as a 3/8
wavelength radiator on 80 Meters and 3/4 wavelength on
40 Meters. On 40 Meters it needed a 4:1 "unun" and on
80 Meters it required a 150 pF variable capacitor in series
with the radiator. On 80 Meters, the bandwidth was not very
wide but it was easy to adjust for 1.1:1 SWR anywhere in

the band.

This end fed wire also operated on 15 Meters with a SWR under
2:1, across the entire band.

Wider bandwidth antennas for 80 Meters are possible.
I have also, at one time, constructed a coaxial antenna
that would give about 350 KHz of bandwidth on 80 Meters.
It's a rework of a Off Center Fed antenna but built with
coax. Coaxial antenna don't tend to be very efficient, but
it does work. The same antenna also covers about 500 KHz on
40 Meters.

I made a scaled down version for 40/15 that also works well.

> btw, rig is ten tec triton iv. now the days when i would
> tune my dx100 into a light bulb, and didn't know (or care)
> what the swr was, look nice and uncomplicated...

I still run all of my Heath gear and still, sometimes, ignore
the SWR and just load and operate. I've never blown up a
final yet, and I still get contacts.

Well, just some more ideas.

Hi Keith:

All of the exact same concepts discussed in my previous post also apply to the situation with a Norton equivalent circuit. In this case, we first need to correctly define the Norton circuit. It must be a circuit which delivers a *forward* current of 1 A to the transmission line. Let's assume that the Norton circuit is a current source of 2 A and a parallel impedance of 50 ohms.

At time T=0, the current source sees a total impedance of 25 ohms and it delivers a forward traveling current of 1 A to the transmission line and 1 A to the internal source impedance. The total voltage across the internal

impedance is 50 V and the forward traveling voltage in the transmission line is 50 V.

The 1 A of current arrives at the open circuit termination and a reflected current of 1 A is created and travels rearward towards the Norton generator. At time T=2t, the Norton current source is still delivering 1 A to the internal impedance and 1 A to the transmission line. However, there is a rearward traveling current of 1 A arriving back at the transmission line input. The total or net current delivered to the transmission line is 0 A (I+ - I-). The total current developed in the internal source impedance is now 2 A. 1 A from the source and 1 A from the reflected wave.

If you draw the steady state Norton circuit, transmission line and all currents you would see a 2 A source delivering 1 A to the source impedance and 1 A to the TL. There would also be 1 A returned from the TL, it is delivered to the internal source impedance.

Perhaps the most significant concept in all of this is understanding what reflected power means to the transmitter or the source. We cannot look at the problem in terms of power delivery. For example, if 50 watts of reflected power arrives back at a matched source, this does not mean that the source must dissipate or absorb this 50 watts of power. We must not approach the analysis with a thought process that requires us to account for 50 watts of "additional" internal power dissipation. It does not happen this way. All that we need to consider is how voltages and currents combine in the source and in the transmission line. The steady state voltages and currents developed within the source are a function of the source voltage or current and the reflected voltage and current arriving back at the source. The steady state voltage and current developed in the source are a net combination of the two. The internal power dissipation occurring within the source is a function of how the voltages and currents develop.

In the Thevenin and Norton circuits, we see two different internal power dissipation but both are correct given the defined source parameters and the reflected voltage and current. Both examples are consistent with circuit theory and transmission line theory. Both correctly describe the affect of the wave reflections in the transmission line. The fact that the "power dissipation" in each example is different in meaningless in terms of understanding wave behavior in transmission lines.

(Cross posting limited to just the Usenet groups that I am subscribed to.
;-))

It used to be illegal, in the UK, to import or own single band 10m gear.
The excuse given was that this was to stop people importing 10m gear and
then modify it for use on 11m.

It was also illegal to buy an illegal, in the UK, 11m rig and to modify it
for 10m. it was, however, OK to buy a legal, in the UK, 11m rig and modify
it for 10m use.

The importation and ownership of single band gear for the 10m band, by
licenced radio amateurs, is now legal once again in the UK. I'm not sure
about the modification of illegal 11m gear to 10m though.

Ann Arbor terminals had a slashed zero as did all of our competitors. The
IBM 3270 and compatibles had a dot in the center. The early computers did
not have video displays, they used ASR33's and other Teletype Corporation
products as I/O. The early computers that used Video terminals carried over
the slash zero as they were called "glass TTY's".

In the "Test Equipment" section of any ARRL Handbook, for the last 20 years or so, is a description of a RF Probe that is ment to be used ahead of a VOM/VTVM. It only consists of a diode, capacitor, and a resistor. They are pretty simple but I wouldn't count on them being very accurate, if that's what your are looking for. Maybe if you had something to calibrate it against, and used a high impedance voltmeter (DVM, VTVM, FET VM, etc.) you could get a reasonable calibration. And, depending on what frequencies it is needed for, construction quality will come into play. The higher the required frequency, the more sensitive it is going to be to layout.

I've got about 100' of horizontal tree free run to put a wire antenna.

(likely a carolina windom variant 80-10 meters)

However, this would mean putting the antenna parallel to my
150amp overhead power feed from the power pole at a distance
of about 10 (closest) to about 30 feet (farthest).

This feed has an uninsulated ground wire and 2 insulated 120VAC
lines, wrapped into one cable.

What amount of interference is to be expected with this configuration?
Will filters reduce/solve interference problems. Any rules as to how
close you can get to such a power line feed?

MUCH THANKS for any ideas....

I find myself in total agreement with Chip on this one. If it is about antennas it should be allowed. The sale of antenna books etc reaches a more focused audience here than in a for sale conference that many of us do not even subscribe to.

If someone were to list a radio or a power supply for example, those objecting would be on firmer ground. Worrying about antenna books on an antenna conference is really "picking fly deification out of the pepper".

If you are referring to the Maxcom "automatic antenna tuner," you may want to know before you obtain one that the one that was Product Reviewed by ARRL contained only a resistive network inside that ensured that no matter what impedance was present on the output terminals, the SWR at the input would be 2:1 or better. It also had a printed circuit board inside that was found to be scrap board cut to fit the space, not actually connected to anything.

There is nothing inherently wrong with the technique; the military uses is to help ensure that no matter what antenna they cobble together, their transmitters will see a reasonable load. The efficiency can be as good as 50%, and as low as a few percent or so.

ARRL members can view the Product Review (November 84) at:

http://www.arrl.org/members-only/prodrev/pdf/pr8411.pdf

> close you can get to such a power line feed?

The amount of interference you can expect can range from almost none to unbearable. If there are no power-line problems, or nearby neighbors with noisy devcies, what you propose can work out well. If there are power line problems or other neighborhood noisy devices, the RF noise can be on the power lines and will couple into the feed to your house. In that case, the proximity of the antenna to the line will probably give you trouble.

It sounds like the antenna will be relatively easy to install, so I suggest you try it and find out whether you will have a problem. If you do, using a narrow filter on CW may help, but on SSB, filtering won't really remove much of the noise. Some DSP filters have "denoising" algorithms, which may help, but these generally work by improving a marginal signal to noise ratio, not by reducing noise. For example, if you have a 10 dB S/N ratio on a signal, it can improve it to 20 dB, making it sound more pleasant, but if the signal is buried in the noise, it will stay buried, even with denoising DSP.

The type of filter that can help in some circumstances is a "noise cancelling" type of filter. This device works by combining out of phase the noise picked up by a sense antenna (located to pick up more noise than signal) with the signal from your main antenna (hopefully designed to pick up more signal than noise.)

The ARRL has a web page on power-line interference at http://www.arrl.org/tis/info/rfi-elect.html. The URL has links to the Product Reviews for noise cancelling filters.

I will add that I would be equally concerned about the safety aspects of locating an antenna that close to your service feed. Do ensure that if the antenna ever comes loose, it cannot fall onto the line.

3202. 80m twin feeder antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-27 00:00:00 UTC
From: Leigh Preece= <mda03@keele.ac.uk>
Message-ID: <8vta99$pu8$1@www1.kis.keele.ac.uk>
Source record: 175655

Hello.

I'm restricted on space at my QTH (as a lot of people are!) and have a doublet that works happily between 40 and 10m as well as a vertical for same. Workable space is approx 70ft from chimney to end of yard with height restrictions due to overhead phone lines.

I recall seeing a website or article that made a 80m band aerial using twin feeder but can't find it now. I think it was similar to an antenna being marketed here in the UK called an 80 plus 2 (80/40/20m) which is a sort of 50ft doublet-ey (!) thing or similar - but definately used twin feeder along its length - obviously to get enough wire out for 80m coverage. Something similar appeared in RadCom Technical Topics, but again the copy is eluding me - meaning its probably a very old but simple design.

(I was advised to run a long loop with a 300 or 450ohm balun but feel this needs height, which I sadly lack - would it work lower to the ground?)

Any suggestions, etc, more than welcome.

Leigh....M5GWH

Hi Leigh, my 80 meter loop (sorta !! it goes everywhere) is only about 6 feet above my house and works fine.. There is a dipole called "Kansas" dipole that is made of ladder line with a third wire tied in the middle of it, that is great on 40 and decent on 80...as I recall it is only 60 feet total length...so it makes a good inverted vee or flat top in 60 or so feet...The loop works better even at a lower height tho, I would think about 16 feet or 5-6 meters would be the lowest you could use it at...it does load other bands well, and if you feed it (loop) with ladder line , especially at 1/4 wave to 40 meters, the put a 4:1 balun it, its good everywhere...73 best of luck...Murray PS...THE G5RV fits your description of short all band I think, are you familiar with it? M

Amateurs have a very privileged status in the U.S. Every other service may only operate type accepted equipment. We can operate any piece of junk that we can buy, build, modify or cobble together, as long as it meets the technical standards of the service. As technically skilled operators, we are expected to understand that our equipment does meet those standards.

The only limitation applies to external power amplifiers below 144, and specifically between 24 and 35MHz, where there are some restrictions on what we can build/cobble together.

3206. G5RV 300 Twin or 450 Ladder ?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-27 00:00:00 UTC
From: "Andrew J. O'Brien" <obrienaj@netsync.net>
Message-ID: <t25nn8c4d3caf5@corp.supernews.com>
Source record: 175659

I have a G5RV Junior which works well and was thinking about putting up a second one, this time the full G5RV. I have some spare 450 ladder line but see in some articles that 300 ohm twin lead should be used. I found this reference to 300 Ohm performance

MHz Twinlead/Coax Junction Impedance 50 ohm Coax SWR
3.8 14.6 + j2.9 3.44
7.2 27.9 - j54.8 4.3
10.125 31.6 + j274 50
14.2 103 - j49 2.6
18.14 44.3 - j290 40
21.3 24.2 + j80.7 7.8
24.95 79.3 + j41.5 2.2
28.4 3049 + j655 64

Anyone know how it compares with 450 ladder line ?

The FCC shows this range as being "private land mobile". A quick search
of licensees here in Oregon shows a lot of transmitters licensed by
McDonalds, Taco Bell, and similar companies, with a few assignments to
local governments. You should be able to get better information by
asking on rec.radio.scanner.

If you're referring to the Maxcom "Automatic Antenna Matcher" - it is
nothing more than a dummy load onto which you hang wire.

If I were you, I wouldn't waste my time on it.

Under 'lift' and sporadic-E conditions, he could easily pull in stations well in excess of 250km, but still rarely hear the station he wants. As you say, Bob, you are unlikely to get more than 50 or 60 miles (say 85 to 100km), and I presume that you also mean under 'flat' conditions. You can probably NEVER get 250 km under really flat conditions, regardless of the gain of the antenna.

The situation is somewhat similar to the reception in the Irish Republic of TV transmissions from 'over the water' in the UK. At UHF, one receiving site (which fed a cable TV system) got pretty consistent, good signals at a distance of about 120 miles (although with occasional deep fading into the noise). However, as the UK UHF TV network spread, problems of co-channel interference began to cause problems. They get the signals by other means these days.

Ian.

On my machine you get a 'ï¿½' like this...
Turn on the 'num lock'.
While holding down 'alt' type 0, then 2, then 1, then 6 ON THE NUMERIC
KEYBOARD (or whatever you call it - you know what I mean - the one which
has the 'home', 'pg up', 'end' etc). After you have typed the '6',
release the 'alt' key.. and up pops the 'ï¿½'.

Note: the 'top row' numbers DO NOT work.

Cecil (W6RCA) did post (some time ago) a list of the interesting
characters which he had found between 'alt0130' and 'alt0255', although
I find that mine seem to start at 'alt0161' (I only get 'ï¿½' before
that). 'Alt0181' is a useful one - it's 'ï¿½'.

There are two problems...
1. I believe that everybody may not receive the 'correct' character -
eg, the 'alt0181' should be a Greek 'mu' - who didn't get this?
2. I haven't worked out how to do this on a laptop where there is no
numeric keyboard.

ï¿½ï¿½ï¿½ï¿½ï¿½ ï¿½ï¿½w!

Ian.

Since a lot of "450 ohm" ladder line is as close to 300 ohms as
it is to 450 ohms, it shouldn't make a lot of difference. Make the
"450 ohm" series section transformer about 10% longer (about 31 feet)
than the "300 ohm" series section transformer .

Approximately every other megacycle (sorry, I'm old) is allocated to the
government in the US. The alternate megacycles are land mobile, but there
are some 330 watt (RF output + maybe a 6dB gain antenna) paging frequencies
in there, and some are around 35 MHz, IIRC. Police Call from RatShack has
some rudimentary information on services and licensees.

>
> (Just being picky . . .)

No - it doesn't remain to be demonstrated. It IS demonstrated.
The reflected pulse performs work for a specific duration. That
is power. The work it performs causes the scope waveform to
change from a flat line - 0 vdc to a level relative to the magnitude
of the pulse, for the duration of the pulse.

You are confusing a *measurement* of power with a demonstration
of power. TDR does not measure reflected power, but it most certainly
demonstrates that there is reflected power. There is sufficient power in
the reflection to cause the vertical deflection circuitry in the scope to
move the beam.

Furthermore, TDR is a practical application, not a theoretical
discussion. In theory, one can postulate an infinite impedance.
One could then discuss a voltage pulse across an infinite impedance
as not being a demonstration of power.

But the TDR is applied to an actual circuit, in which there must
impedance. If you have a real impedance and a voltage across it,
current will flow and power will be consumed.
Our voltage - the reflected pulse - across an impedance
must result in current flow - and thus, power. The 'scope presents
an impedance to the pulse and thus consumes power. It demonstrates
that power exists by vertical deflection.

We did "steal" all the signal on one occassion: As the detachment commander of an AN/VRC-142
HF Radio teletype detachment with the Canadian Forces Signal Branch I was deployed to a small town south of Winnipeg Manitoba. We were working off whip (16') @ 400 watts with a AN/GRC-106A.

Everytime were went on transmit, we blew the entire town off the local television station; needless to say we were not to popular, as we stole thier tv signal. <Grin>

: Bill Nelson wrote:
:> A signal strength meter in the far field is then used to peak radiated
:> power.

: I can see how that would work with vertical antennas, Bill, but
: what about horizontal antennas?

Sure. The polarity does not matter.

You cannot get a good indication of maximum radiated power by measuring
in the near field - or by measuring the rf currents with an inline meter.

The former will produce all sorts of strange results - and the latter
will only tell you how much power is coupled into the antenna, not whether
it is radiated or lost as heat.

I suspect that you are concerned about the earth conducted portion of
the signal. It complicates matters, but the earth conducted and space
wave portions will rise as the antenna is peaked for maximum radiated
signal.

Source record: 175766

NOW AVAILABLE, Program "LOADCOIL.exe"

COIL LOADED VERTICAL OR SLANTING ANTENNAS

This program does a job similar to program Vertload. In some respects it is a more accurate model. It is easier to use - input data is entered in a more logical form and requires less thinking about. Assistance with coil design and performance prediction are the principal features.

In particular, coil height is entered as a percentage of overall antenna height and there are facilities to 'slide' the coil up and down the antenna when searching for the height of maximum efficiency. Overall height, coil length, coil diameter and frequency can also be continuously and rapidly varied in fine incrememts via the keyboard.

Output data is in a more interesting form. The effects of the coil's self-capacitance on self-resonant frequency and on Q when the coil is mounted too high up the antenna are also shown.

The program covers a wide range of antenna proportions, from VHF via 10 to 160 metres, vehicle mounted or at base stations. Anywhere where a vertical or slanting (or perhaps even an inverted L antenna) is appreciably shorter than 1/4 wavelength and performance would benefit from insertion of a loading coil somewhere along its length.

A detailed description of how the location of the coil affects operation is included. Data is provided to assist users to crudely estimate input resistance of a set of buried radials.

One small binary file: 52 kilobytes. Download from website below in a few seconds.

While I agree he will have difficulty unless both he and the transmitting
station are on large mountaintops, he's talking about a distance of about
210 miles, not 2000. There are commercially available high gain FM
antennas, at least in North America. I bought one in Canada for about a
hundred dollars a decade ago, but line of sight at ground level is
generally about 40 miles only. You'd be lucky to get much more than 50 or
60 miles unless one end or both had significant elevation.

Today we would call it a font or glyph variation. It was printed, when
0x30 was sent to the terminal (or 0xB0 if odd parity was used). There
was not a separate character code for slashed zero.

The print cylinder (or whatever it was called on ASR-33) did not
contain _both_ the ordinary zero and the slashed zero.

Thus, the slashed zero did not appear in the character set as a
separate entity but rather as a glyph variation. The same applies to
the early home computer character generators with _only_ the slashed
zero (but not ordinary zero) in the character set that others have
commented in this thread.

Today, would you considered a zero printed in italics to be a
different character when printed in boldface :-).

Quite correct, but if you think about it, every conductor in the area
is going to pick up and re-radiate some of the energy, even the
random-length, non-resonant piece of iron pipe or whatever. Their
total contribution to "absorbing" power is far greater than that of
any lone antenna.

Hi George,

If you want to look at the "efficiency" of broadcasting consider the
following scenario.

Give every man, woman, and child in this world a receiver and antenna
(some several billion at last count).

Give every receiver a budget of your total power emitted such that
they get 10 dB over S-9.

Now transmit your 100 Watts.

Now supposing every receiver did in fact exhibit a 10 over S-9, you
have lost approximately 98 Watts to heat, or the infinite black of
outerspace.

Thus at 2% efficiency your have provided near broadcast quality signal
levels to every living soul on the entire planet for a 100 Watt
investment. Some may argue that this "lost" signal may fall on ground
that is not monitored - fine, give every living soul 2 receivers and
two antennas. Now the efficiency is up to 4%. Give every living soul
10 rigs and antennas and efficiency will rise to the astounding figure
of 20%.

Needless to say, most of the planet has absolutely no interest in what
you have to offer, so efficiency will plummet. Which is to say that
our newsgroup's penchant for waxing poetical about the mystery of the
dissipation of energy (or non-dissipation) is something less a mystery
than a fact that all energy is eventually dissipated EVEN IF NEVER IN
THE FORM OF HEAT.

Hi George

I think you will appreciate this aside.

My son is an engineer at one of the big three.
In a conference where solar energy cars were being discussed, one of the engineers actually brought up a topic much similar.
If all the cars were run on solar power, rays that would be striking the earths surface for warming would be used up to power the cars and the planet would start to cool down and we would go into another ice age.
Nothing was said about the heat generated by the motors on the cars though.
We all got a good laugh at it!
Wonder which college he graduated from?

But the signal is not being "absorbed" (like a sponge with water), the
electric field is spread out all over the ether (love that word, excuse me).
So YOUR antenna is intercepting the electric field where IT is, and MY
antenna is intercepting the electric field where IT is, and so on. We are
"touching" different portions of the field and therefore you should not be
able to "suck away" all the energy from me -we "touch" it at (essentially)
the same instant in time.

Now, if the RF had weight and everyone on the US side received the signal,
it might tip over and not even reach into europe - but - hey, forget I said
that before we go down that path. It's all hypothetical so we can make up
any outcome we like - kind of like Gore/Bush in some ways. But I digress...

3236. Re: Modeling antenna wire in plastic tube

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-28 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A24126A.C304D67F@eznec.com>
Source record: 175526

The radiator diameter should be modeled as 1.5 mm. However, the fishing poles will make the electrical length of the wires slightly longer. Standard insulation makes a difference of roughly 3%, so I'd expect the loose-fitting fiberglass to make a considerably smaller difference. I'd make the model wires about 1% longer than the real antenna wires, as a guess. EZNEC has no way to account for the effect of the nearby dielectric other than your manually lengthening the model wires, and even a small error in parasitic element calculation can make a big difference in the pattern of a small beam. So you should expect to have to do some minor adjusting of the real antenna after analyzing with EZNEC.

I assume you're using the demo version, since my data base doesn't show that you've purchased the full version. Additional error will likely be introduced due to the limited number of segments available in the demo version.

Really!...not in Canada, one can guess why the restriction though...I think it's the Clipperton linear amp that has a choke in the final to prevent transmission around 10 meters somewheres (maybe the whole band?...)

>antenna is intercepting the electric field where IT is, and so on.

In physics classes, there is a well known demonstration of the
propagation of waves around obstacles using water and a rock. As the
wavefront passes the obstacle, there is a refractive effect which
"fills in" the shadow of the rock and after some distance, the
original waveform is re-created. The "filled-in" area has less power
present than the original wavefront would have contained had the rock
not been present. If my antenna is in front of yours and absorbs some
of the power present, your antenna will receive less.

In the real world, I'd guess the difference would be so small as to be
immeasurable, but still non-zero. Isn't hypothetics fun? :-)

Sometime in the 70's or so there was a box marketed as an antenna tuner when actually all it was was a sealed (solid epoxy) box containing a number of resistors.
Granted it presented a low VSWR to the transmitter but didn't radiate too much RF either. I think it was named Max Com. QST did an evaluation on it.

I hope this is what you are not looking forward to finding. If so then buyer beware.

3247. Darwin in action

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-28 00:00:00 UTC
From: KG4FGN <kg4fgn@mindspring.com>
Message-ID: <901mbo$348$1@slb6.atl.mindspring.net>
Source record: 175537

OK, I'm hoping someone else out here has tried this idea and can give me some pointers.

We've all heard the Darwin Award about the Lawnchair guy who hooked some balloons to a lawn chair and wound up floating to 12,000 feet. (If you haven't read this hilarious story, go to www.darwinawards.com, click on honorable mentions, vintage years, and click on Lawn Chair Larry).

So I was chuckling with my wife over the turkey holidays, remembering some of the Darwin stuff. It got me to thinking though, if it worked with an idiot, it would probably work OK for an antenna. So I'm thinking, if I built an inexpensive homebrew antenna (maybe a Yagi or a simple ground plane) and hung it off the bottom of a weather balloon, and fed it with some light weight coax, I could run it up to 100 or 150 feet and maybe do some interesting dx type work on 2 meter. Might also make an interesting addition to field day.

So what I really need to know is:

1) Where the heck to I get a weather balloon or other similar balloon that would hold the weight of antenna and coax?

2) I'm thinking of getting a canister of helium to fill it with. Any other suggestions? I thought about using a hot air system, but the mechanics would be a bit harder to work out.

3) Any other tips or things I should look for? I want to learn from other people's experience.

If you think I'm nuts, my wife agrees with you. But what the heck, a guy has to have fun...

Robert / KG4FGN

Source record: 175541

Doesn't have to be a Yagi, it was just one idea I thought of. A vertical dipole or other antenna would work, it was getting it up high was what I was working on.

As for steering, it could be a problem on a windy day. I did have a yagi hanging from a tree limb for a while though, I had a pole coming off the bottom. From it came a rope that I anchored to the ground, keep the antenna in the vertical position. I tied a second rope to the back, for steering which once I pointed it in the right direction tied it off. This did a surprisingly good job of keeping the antenna oriented correctly. Sure, it wobbled just a little bit on a very windy day, but stayed pretty well put. I envisioned a similar system for the balloon, if I did wind up using a yagi on it.

As George can tell, this idea is in it's very early stages so I'm still working out the kinks. The site Chip mentioned (EOSS) is interesting, but they are going way over what I planned. They are launching an entire radio 100,000 feet in the air, I'm looking to put up an antenna 100 to 150 feet up.

I checked out Edmund, they didn't have any weather balloons but the EOSS site did have some links to balloon supply houses, I'll be checking them out when I can. Most of them though, seem to be made for carrying a large payload (45 lbs) up to 100,000 feet. I'm looking for 10 lbs or so at 150 feet.

I'll also follow up on the idea of finding where car dealers get their balloons from, they sound ideal for the job. (Another friend, KG4KCM suggested that earlier today).

Thanks for the ideas so far, if anyone has done it, would still love to hear from you!

Party supply store. But beware, even balloon grade helium in this quantity
isn't going to be cheap.

> 3) Any other tips or things I should look for? I want to learn from other
> people's experience.

Pointing a yagi would be a problem; better something like a verticle dipole.

I friend and I went through some rough calculations on what this would take
given the weight and cost of everything. We came to the conclusion if you've
got money to burn, OK, otherwise a kite would be more practical unless you
are willing to take the risks of a hydrogen balloon (more lift for the buck).

The kite could also serve as the "frame" for a wire antenna.

There was an article in QST a few months back about building your own
kite on steroids for doing such things.

->If you think I'm nuts, my wife agrees with you. But what the heck, a guy has
->to have fun...

At one time we used a copper foil dipole antenna on a regular old (large) kite from the five and dime and used RG174 as the "string" as well as the feedline in rather decent winds as an emergency sailplane out-landing device for crew car communications.

It worked well with large kites and moderate winds. Things generally didn't do so well when the sun went down. YMMV.

Why not do my setup. A comet or so for 2/70 on top of the car and the
ATAS-100
on a little frame on the back of the car. (left side that is)

What I did is find a bumper mount spot and made a good solid plug on it.
Than drilled a smaller hole than needed and used a grinder bit to make a
flush fit for the ATAS. Now it seems to be part of the car ...

One bummer though, I got small kids and the car is a station-car, but
the
setup itself is neat. Good addition to a ford escort.

Now to get the mounting kit and find a quicker way to change the radio
fron
in the car to in the house. I'm considering a sort of additional
backplane
to make it more manouverable for 'location-swaps'

Yep: "analysis" in quotes is exactly right. This is the time I start to think about quantifying things and doing some sums, but I can just never remember where I left my slide rule and PhD!

I have no doubt that some energy may be re-radiated from the receiving antenna but as sure as (Vsquared/R x time) is energy, SOME energy is gonna be removed from the field by each antenna in it, if there is the smallest bit of R in the receiver input.

As stated, that's not my concern. I am pointing out that if you send me , at fractenna@aol.com, a list of books it will likely be purged before read.

I have made efforts to keep the e-mail down on this account , generally, to those who are friends or colleagues. For example, hams that have questions on fractal antennas can (and do) what they have for two years now: post it on the fractal antenna reflector.

The harassment--both on and off NG-- has cut down dramatically! For those who continue with it, the legal system will take care of the rest, for I have asked them, then requested of them, that they desist. Certainly the bevy of hams that find me an unsolicited pen pal will stop. I think that is a healthy move for them.

Rob--

Sounds like a good suggestion for a down-and-dirty antenna for many uses, as well as ones where you're not too concerned if you don't end up coming back with it. :)

What do you feel might be a guestimate of the power handling of such an antenna?

Thanks

I have not done that here,I have mine on a hump mount and use it base/mobile,
BUT It is possible to do that I would think(deminsions 6.3"x2.2"x8.0"). You
will need to make sure the fans ar unobstructed, for 2 reason the fist being
the most obvious and thats air flow, the second is that the fans will make
quite a bit of noise if they are blocked

I'm interested in other
>install suggestions.

>about other options, such as antennas with multiple coils such as Cushcraft
>or "Spider"-type antennas?

The ATAS 100 is a good preformer for what it is. I have had the oportunity to
use one and found it to do a pretty good antenna for 40-6 meters, and did ok on
the local repeaters on 2mtrs/70cm. For a SMALL antenna is does an excellent
job. I have always been a band hopper and think that having to stop and change
a coil or rewrap an OUTBACKER would be more trouble then its worth espcially
since the ATAS 100 is cheaper then the OUTBACKER.

Hi Bill,

I agree there is no free space antenna. Anyway I do not understand how the mount or coaxial cable affects the power dependence of the fields radiated. If I model an antenna with NEC and put some metal structure close to it (rain gutter or so) I still would expect the fields to increase with square root of power (actually I never tried it). The mount, cable etc. will all respond
to the field, charges and currents will be induced of course but I would always expect the square root law as long as no arcing somewhere or nonlinearities (e. g. corroded junctions) occur.
If the field(s) do(es) not depend on square root of power, does that mean that
my antenna produces harmonics due its nonlinear response ?

Where is the error ?

I agree that a toroid balun is a potential source of nonlinearity.

To reasonable precision, free space antenna designs most certainly exist. If fed externally, there is some disortion from the coax. But again, the issue is the degree of precision you need.

Also,I suspect you are misunderstanding the inverse square law. This applies only in the far field. For example (not an antenna one): as you go under the surface of the earth, the gravitational force goes as 1/R, not 1/R^2. It sounds like the close by structure you describe are in the near field of your antenna.

Hi all,

thanks to all who responded, just was to find out what it was.
The signals monitored where narrow band FM mostly, some fo them where
broadband FM.

Apart from the allocation of some military service the frequency range
35 to 35.2 is allocated to remote control. The people at this club where
just astonished to find their planes falling from sky :-(

> coils and traps. Is this true ?

No.

HTH de Dave (G0DJA)

Oh, you wanted more details? ;-)

The only thing which will be able to 'burn out' coils and capacitors are exceeding their electrical ratings.

So, if you pass more current through than the wire of the coil can carry, then the wire will break. Like a fuse does.
If you put too high a voltage across a capacitor, then the dielectric will break down and the capacitor will fail.

A antenna tuner is not able to do either of these things, as it is a collection of capacitors and coils which match one impedance to another.

However, if you manage, by adjusting the matching between the rig and the feedline, to pass enough energy to the antenna so that the current and/or voltage ratings of the antenna are exceeded, then you will 'burn out' the coils or capacitors. But that's a user error.

P.S - There was something strange about the original message. I could not 'Post' a reply, only send a reply to the author. Other threads in the NG did not have this problem..... I, therefore, have started a new thread to post the reply.

3270. Re: Your taking all the signal...

An antenna does not reach out and suck it all up. It takes only what energy is available from a very small volume of space roughly 1/2-wavelength in diameter. And at least half of it, usually more, is re-radiated.

To soak up much of the power from a transmitter requires it to be located at the centre of a large sphere with the surface of the sphere covered with matched dipole antennas with directors and reflectors and with no gaps in between. Even then it would be leaky.

Reg.

10 & 12 will behave like 6m does now for the most part, activity will be sparse on 15 although the band won't completely die and will be always worth tuning. Thus the cheap Radio Shack 10m xcvrs will disappear from the shelves again until the next high rolls around, etc.
>
Historically activity and competition have also increased significantly on the low bands during the sunspot lows. The basic message being that if you aren't equipped to get on 160/80/40/30/20 or some combination thereof plus have the ability to dredge up and handle weak signals you'll find it considerably more difficult to find qso's during the lows. "When the going gets tough the tough get going" scenario. Get some wire up, it's coming.

This is incorrect information. If you were to assume that you had a mismatch to the antenna, the only result of a tuner would be to allow more power to be transferred to the antenna. If the antenna is operated within it's power limit the tuner has no effect.

: Certainly the bevy of hams that
: find me an unsolicited pen pal will stop. I think that is a healthy move for
: them.

Replying to Usenet posts in private email is a perfectly legitimate
form of participation in a newsgroup. It is particularly recommended
in instances in which a response is not likely to be interesting to
the newsgroup as a whole, and even more so as a courtesy to everyone
concerned when disagreeing with a point made by the original poster
(except for points central to the newsgroup's theme).

Almost everyone I know of considers participation in newsgroups via
private email to the poster, when appropriate, to be not only wise,
but even...healthy.

Anyone who voluntarily posts to a newsgroup should not be at all
surprised if they receive private email as a result. The only two
ways to avoid it (that I know of) are to post anonymously (not
recommended as accepted netiquette in most cases) or not post at
all.

[This followup was posted to alt.ham-radio.am and a copy was sent to the cited author.]

Well, sort of! I asked the fellow at QRZ.COM to restart the e-mail list, "HAMTRANS". Some of you (like me) may remember it. I never was able to take advantage of it, apparently because it was poorly moderated, and some W7 something-or-other ripped off a bunch of folks. Well- I'm not here to rip anyone off- and I hope there are others who, like me, enjoy buying, selling, trading, swapping, whatever, amateur-radio related items, some of which are too large, too heavy, or bulky, and it is unreasonable to ship these items. Maybe it's a small item, but perhaps you can can't afford the shipping due to fixed income, but want it, and the shipping just pushed you over the edge of being able to afford it? Well, we all need to help each other!

When you plan a trip, please try to post your itenerary to the list if you don't mind transporting an item along your drive path. If someone is buying an item, and lives along your drive path, they will contact you and ask for your assistance. In return, other list members will make offers to transport items for you sometime (we hope this is the way it's going to work).

Now- some VERY simple rules:

1. Don't expect the transporter of your item to box it up for you. Your seller should have your item ready to transport, JUST AS IF IT WERE GOING TO BE SHIPPED UPS. This will offer some protection against scratches and damage during the shipment, and will help your driver not get muck all over his/her vehicle or ruin the interior (we hope). If damage occurs to your driver's vehicle by your package, you should voluntarily pay for the damage. I sincerely hope that any damage claimed would be so obvious so as not to leave any room to debate cause and effect so as to avoid a lawsuit, but any problems are between YOU AND YOUR DRIVER.

2. Don't expect your driver to make a side-trip off of his/her anticipated drive path. Have your seller meet them along the interstate.

3. Get your seller and driver together on a sked utilizing whatever means possible so that nobody has to sit at a gas station waiting for someone to show up that never does, or is an hour or so late. If your shipper misses his drop to your driver- you may not get a second chance! If your seller fails to meet the driver on sked or can't make the drop, it's up

to *you* to make other arrangements. We in amateur radio work on an honor system. Don't screw it up for everybody!

4. Meet your driver delivering your goods to correlate with his/her drive plan. Don't make him/her go out of the way to meet you! You're the one in the shipping predicament, *NOT* your driver! If your driver is going one state away from your location, perhaps you at least got the item from the "other" coast, and YOU will have to drive to meet them!

5. Understand that this list is in no way responsible if you trust the "wrong" person. There are schmucks in every walk of life. If they rip you off, you should seek help from the police, NOT FROM THIS LIST! (Except to inform the rest of us not to trust the jerk that ripped you off!)

6. Mis-scheduling on your part does NOT constitute you being ripped off! You should be willing and able to pay shipping for your item from your drivers destination back to your location if your paths fail to cross as scheduled. And keep in mind that you will be paying for UPS (or whomever) to come out to your drivers location with a "call tag" so it doesn't inconvenience your driver by having him locate and drop your package at a UPS drop point.

7. IN BIG CAPITAL LETTERS! THIS LIST IS IN NO WAY RESPONSIBLE FOR ANYTHING RELATED TO WHAT HAPPENS TO YOU AND IN NO WAY GUARANTEES THAT YOU WILL HAVE A PLEASURABLE EXPERIENCE WITH SHIPPING A PACKAGE OR THAT YOUR PACKAGE WILL EVEN ARRIVE VIA THE HAMTRANS NETWORK!!! IF YOU RECEIVE A BOX OF BRICKS INSTEAD OF THE RADIO YOU PAID FOR, THEY WILL BE YOUR BRICKS!!! THIS LIST IS NOT YOUR PERSONAL BABYSITTER! YOU ARE PRESUMED TO BE AN ADULT AND IT IS PRESUMED THAT YOU CAN TAKE CARE OF YOUR OWN PERSONAL AFFAIRS!

8. If you are dis-satisfied, SEE RULE NUMBER 7!!!

If you find this e-mail list interesting, you may subscribe to:

HamTrans@qth.net

As I am not well-versed in e-mail lists, even though I requested the creation of the list, I believe that to subscribe, you send an e-mail to:

majordomo@qth.net

with a subject line of:

SUBSCRIBE HAMTRANS

If someone else knows better, they can correct me. If you have comments, suggestions, or whatever, please remove the NO before the @ and the SPAM after the @ in my e-mail address to reply. E-mails sent without taking care of these two minor details will be bounced. If you can't figure out how to click and use your backspace key in the address box, you probably don't need to be reading this in the first place. Comments to the newsgroup may or may not be read by me. I'm a busy person.

Fractenna <fractenna@aol.com> wrote:

: Also,I suspect you are misunderstanding the inverse square law. This applies
: only in the far field. For example (not an antenna one): as you go under the
: surface of the earth, the gravitational force goes as 1/R, not 1/R^2. It sounds
: like the close by structure you describe are in the near field of your
: antenna.

Ah, so, we can't count on the near field varying as we might predict, with
regards to distance from the antenna.

However... can we count on the near field strength to increase in step
with increased power to the antenna?

I suspect that some of the confusion here is that some people are thinking
about the case where the goal is to "tune" an antenna in the sense of
adjusting the length, spacing and orientation of its elements, with a
goal of optimizing its radiation pattern, while other people are thinking
about the case where the goal is to "tune" the antenna *system* in the
sense of matching the feedline to the transmitter (or perhaps the
antenna...but let's keep things simple and assume that some of us are
thinking in terms of a standard tuner-in-the-shack set-up).

If no adjustments are made to the antenna--can we count on near field
strength to vary in step with the power delivered to the antenna?
Never mind whether it varies inversely proportionally to R, or R^2...
Never mind whether it varies linearly at all with respect to power
delivered to the antenna (though I suspect it probably should)...

Couldn't we at *least* count on the field strength to reach a maximum
when the power delivered to the antenna reaches a maximum, as we tune
our tuner for the best match of transmitter to transmission line?

I suspect that the only precaution we'd have to take to be able to
count on things working that way (again, assuming a standard tuner-
in-the-shack set-up) would be to take the field strength measurement
from somewhere closer to the antenna than to the shack. Otherwise,
we might be observing a peak in "RF in the shack" rather than RF out
to the antenna system. As long as we avoid that, can we count on a
maximum of field strength to coincide with a maximum of power delivered
to the antenna?

IF it's a yagi, as the original questioner posited, the bandwidth of
the power absorption would be fairly narrow, and if the coax were
unterminated, the absorption would be near nil. It's a good question,
though.

3283. Re: G5RV 300 Twin or 450 Ladder ?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-28 01:03:04 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8vv041$e4g$1@plutonium.btinternet.com>
Source record: 175579

With a G5RV type of antenna the only noticeable difference
between a 300-ohm and a 450-ohm feedline would be a
different set of tuner settings for the various bands.

If it was possible to measure accurately enough, on the
average, there would be a fraction of a dB less loss using
the higher impedance line. In fact, a 600-ohm open wire
line would have even a slightly lower loss on the average
taking one band with another. And another set of tuner
settings of course.

Provided, of course, the feedline wire gage remains about
the same as the impedance is stepped up. If this is true
then feeder loss halves as Zo impedance doubles. But
hardley enough for the fellow to notice at the other end
unless you switch all the way from 50 to 600 ohms.

Again on the average, taking one band and one frequency with
another, the SWR's versus 50 ohms are a little lower using
450-ohm line. So go for it if you already have some.

Quality control of line impedance at the factory is rather
poor. Zo could be +/- 15% from its nominal value.
So there's not much point in being too concerned about
particular values of SWR at particular frequencies.

To answer ALL your questions on behavior and performance of
dipole antennas center-fed via ALL sorts of lines of ALL
sorts of lengths, download program VARNEY from the website
below. If your line is exactly 450 ohms it will also predict
your tuner settings. Downloads in a few seconds. Not zipped
up. Run immediately.

VARNEY's the one you want.

>From: "Kirby Cave"
> i'm not married

I began to question the use of baluns with dipoles in the 60's when my W2AU bulun was found to be the cause of serious TVI when I operated on 10 meters. Do you really need one at all? Fairly easy to tell. Check your resonant frequency with the balun in. Take it out, an put the dipole back in the same position. Is the resonant frequency essentially the same? If yes, the balun isn't doing anything except adding some loss (and distortion, if TVI develops). If the resonant frequency became lower, the balun WAS keeping your coax from becoming part of the antenna, and it might operate better (and with less RF in the shack) if you kept the balun in. If the resonant frequency got higher, I don't know what is happening. 73, Andy

Hi all,

a friend of minr lost a remote controlled model airplane a few
weeks ago.
The frequency he used for the remote control is close to 35 MHz.
Because
all electrical circuitry was working he asked me to find out,
what might
be the reason, IE if there was any interference possible. Apart
from the 3
rd harmonic of Radio Jordan I found some american accent radio
traffic
between 35 and 42 MHz. Since it sounded like american CB stations
here in
europe (you hear tens of stations at a time), I was not able to
find out
what it was. Could anyone tell me what kind of service allocated
there ?

Nobody could possibly do more damage to your reputation than you have done entirely on your own. And nobody, including myself, is holding a gun to your head and forcing you to keep from your profession, whatever that might be since you lost your "position". Perhaps you should spend less time trolling the newsgroups and mail lists.

You have left a significant trail of breadcrumbs everywhere you've gone. Nobody put them there for you. You did it entirely on your own. They are in the archives of the antenna mail list, the NEC mail list, and AntenneX for everyone to see. Publicly, in the case of the latter, and with a public statement as to the reasons for your involuntary removal, almost identical to those given for your ouster from the antenna mail list.

Odd how history keeps repeating itself wherever you go. The open harassment, refusal to engage in legitimate discussion, the threats of lawsuits. It's all become too predictable.

: Isn't the near field proportional to square root(power) ?

Not necessarily. If the antenna was totally in free space, it would be
true. But that will never occur - for example, the coax is there feeding
power to the antenna. Any mount will also affect the signal measured.

It gets even worse for a multiple element antenna.

Source record: 175592

Hi to the group... I'm looking for input, advice, suggestions, comments, anything at all relating to installing the Yaesu FT100 in a Honda Civic. Mine is a 1999 Civic sedan. I've got the stock factory am/fm radio and the empty space beneath. Some have told me that the FT100 will fit right in that empty "DIN" space just fine. Has anyone done that? I'm interested in other install suggestions.

Also, what about antennas? The ATAS100 is a bit pricey (but then, so is the Outbacker) and I've read mixed reports on it. It "works great on all bands" all the way to "fine on HF but sucks on 2m/440". One would think that monoband whips ("hamstick" type, etc.) would be the best way to go, if you didn't mind switching antennas every time you wanted to change bands... How about other options, such as antennas with multiple coils such as Cushcraft or "Spider"-type antennas?

I've pretty much made up my mind for the FT100 as opposed to the IC706, and if I can get a nice clean in-dash install with the Yaesu, even better!!!!

Comments? Come one, come all!

3297. 80m delta loop

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-29 00:00:00 UTC
From: John Harper <ae5x@optonline.net>
Message-ID: <ABcV5.354691$4d.44356788@news02.optonline.net>
Source record: 175469

Hello, I'm planning to install a delta loop for 80m (3525 khz). According to the formula 1005/Mhz, each side of the triangle should be about 95.5 feet long. I only have room & height for about 75 feet per side and plan to load the bottom side of the triangle (horizontal section) with two coils - one at each end of this section. Is there a formula to determine how much inductance each coil will need in order to bring the antenna to resonance on 3525?

Thanks and 73,

Hey, that's just local residential powerlines. If you tried this in the right area, you'd be able to experiment with 230 kV, 400 kV, or even 700 kV overhead lines. With those, it wouldn't matter whether your feedline had an insulating jacket on it or not. And you would have a good shot at the Darwin Award...

For a surplus balloon, go to Fair Radio Sales. However, I've used
them and I didn't like the way even a slight breeze would blow them
back to earth. I've enquired about a surplus advertising kitoon.
Sometimes these things are made with the wrong stuff written on them.
If you don't care what it looks like, you may find it will meet your
needs. If I remember correctly from the last time we investigated
this sort of thing, we found it cost around $250 (without helium).

>2) I'm thinking of getting a canister of helium to fill it with. Any other
>suggestions? I thought about using a hot air system, but the mechanics would
>be a bit harder to work out.

Go to a Welder's supply shop. They have helium in bulk.

>3) Any other tips or things I should look for? I want to learn from other
>people's experience.

WATCH OUT FOR STATIC CHARGES!!!! This is not the kiddie stuff you get
from walking across the carpet. This can knock you off your feet and
possibly even kill you. Use an RF choke or a high value resistor to
bleed this charge to ground.

>If you think I'm nuts, my wife agrees with you. But what the heck, a guy has
>to have fun...

I'd suggest using a kite because that way the antenna can be fixed in
some general direction. Also, do not use the coax to keep the
kite/balloon tethered. Use good dacron kite flying line. (Available
from In To the Wind). If you're looking at kites, a large Delta can
be had for around $70. It's stable and it's a good lifter.

I can also relate that I have a Stratoscoop III kite and although it's
a very heavy lifter, it's not nearly as stable as I'd like. I prefer
my 9' delta over it for this sort of thing.

Keep the kite/balloon weight under 5 pounds or you'll need to have a
discussion with your local Flight Standards District Office before you
launch. Read Federal Aviation Regulations part 101 (it's short and
quite understandable) for more details.

That's most of it. I'm sure others can tell you anything I've left out.

Hi OM,

Other good pointers found here. To your point however I would add
that the balloons I have seen that manage wind well are those designs
that look like dirigibles. In other words, they exhibit some airfoil
property. I've seen these "fly" into the wind, but with stiff winds
they do a bit of thrashing (flying in a figure 8 pattern). On the
other hand, round balloons just lay right down.

I thought I remembered reading about a 160M antenna supported by a balloon on the one end in QST. It was a full length vertical or something like that. It was used to work some contest and it worked so well that some people were accusing the owner of using illegal power. I can't find it in the ARRL index search and was wondering if anybody knew where I had read that.

Kites can be built that will lift one whale of a load in just a light
breeze.
I built one, using thin wall conduit for a frame. It broke a 1/4 inch rope
in a good breeze. (not a real windy day)

When I was a kid, the local JCs would have a kite building contest.
Each year they would build a monster that was flown from the back of a
pickup truck.

The line was cable and mounted to a reel on that truck.

One year the wind got to be a little more than expected and the thing
started dragging the truck across the field. Gusts were actually lifting
the rear wheels.
They finally had to cut it loose.
Admittedly this was just a 1/2 ton pickup and not one of today's monsters.

They do require lots of space away from power lines though.
The kite may be flown from one location while the station my be located
under the kite.

Just remember to give at least a half mile clearance down wind and a quarter
mile to the sides.

Hi Berken,

The Field Day before last I witnessed one of the group launch a
halfwave vertical with a balloon. It was a standard weather balloon,
but during the evening hours when propagation was coming up and wind
going down. He used a laser based rangefinder to measure out the
length of radiator and had a monster LC circuit at the feed point to
match Z. Reports all around were impressive, he was the big gun as
far as they were concerned.

3306. More tuner questions (with ladder line)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-29 00:00:00 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <3a25ae54_1@news1.prserv.net>
Source record: 175478

Some weeks ago I asked questions here about connecting a dipole fed with ladder line to a simple antenna tuner (without a built-in balun). Everyone who responded suggested a "current choke" balun. I ordered toroids from Palomar and can report that the arrangement works well.
Thank you to those who responded.

I have a somewhat more ambitious design for my next antenna, taken from the August 89 issue of QST. It is a 20m loop, mounted in a diamond configuration, fed at the bottom (ladder line again), with a relay to open/close the "top" of the diamond. The goal is to use it for 30-10 meters. The QST article indicated that opening or closing the top of the loop made substantial changes in the "takeoff" angles on various bands.

An editorial footnote in the article recommended against using a current balun because the antenna impedance might be "several thousand ohms" in some combinations of frequency and open/close options. The article said little about how the ladder line should be fed. Any suggestions? I assume I could use any of the current tuners that have built-in baluns (but not of the current choke variety). Is this reasonable? I will be running 200 watts maximum. Would a 4:1 balun in "front" of my tuner do it? (This would be more convenient, allowing me to run coax for about 20 feet to get out of the house.)

I have heard similar questions from other hams, so responses on this newsgroup might be more helpful than direct responses to me.

Bill Ogden
W2WO

(If I can arrange it, the diamond loop will be attached to the top of a 65 foot aluminum pole that, in turn, will be a base-fed 80/160 meter vertical; but that is a future goal.)

You can vary the length of the ladder-line to get a reasonable
interface to a current choke/balun at the tuner. Many hams are
doing just that to obtain an impedance that their built-in
tuners are happy with.

Jake is right on the regulations on heavy kites. In the same regs, there is
also a limit on balloons that limits them to 105 cubic feet of gas. Quite
small actually. Any larger and authorities have to be notified before
launch. Large kites and balloons are limited to 150 feet or less AGL.

3312. KLM JV2X or JV220X blueprints nedded

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-29 00:00:00 UTC
From: AK <nobody@nowhere.earth>
Message-ID: <902ooi$6u6$1@newssrv.otenet.gr>
Source record: 175558

Hi,
I need to construct a circular antenna to transmit FM (radio).

Does anyone have any construct instructions for the KLM JV2X or JV220X models?

It would be great also, to sent me instructions for similar antennas.

TIA

3313. Best way to improve car FM reception?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-29 00:00:00 UTC
From: Sodah <sodah5@home.com>
Message-ID: <1q7V5.723352$8u4.11790152@news1.rdc1.bc.home.com>
Source record: 175559

One of my preferred FM radio stations which I listen to when in my car, happens to be a fringe station (i.e. far away), and consequently often fades away and/or has lots of noise. How can I go about improving my reception for this station: (1) Install a booster amp? (2) Install a larger (or additional) antenna (i.e. to increase antenna surface area and height)? (3) Opt for a more expensive, higher quality FM receiver?...
Also, what does an FM filter do exactly and would a filter (of this or any other conceivable kind) be of any use -say in combination with any of the above- as far as reducing unwanted noise?

Thanks in advance,
Sodah

Just because the miltary is "allocated" 35 to 35.2 doesn't mean that they stay there. Most of their rigs will tune a much wider area, and the fact that you were hearing "North American English" tells me that it was probably military in nature.

I've heard our military all over the place here in the US, including the ham bands (6m is common), the National Guard seems to be the worst offender. They don't follow allocations very well.

I'd have someone bring a scanner to your flying sessions in the future, and monitor the frequencies in use. If you hear voice traffic, it's time to move to a different channel.......

Good luck!

3315. mobile antenna swinging mount...??

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-29 00:00:00 UTC
From: Fred Davis <fmdavis@nortelnetworks.com>
Message-ID: <MPG.148ee387dbb36cfe989907@carnews0>
Source record: 175561

Hey all,
Years ago I had a mobile antenna mount that would swing the whole antenna into the trunk. This "fold over" mount was very handy when entering low-height areas and also to hide the antenna when parking in less-than-desireable areas.
Basically the mount screwed to the inside lip of the trunk and would come up inbetween the trunk lid and the body of the car.

Anyone know if these mounts are still commerically available anywhere?

There is also GEOCLOCK with the HAM RADIO PACKAGE. But it is a little
pricey.

Many logging programs in the same price range have a similar map feature!
See DX4WIN and LOGIC (www.hosenose.com), etc...

The web page for Geoclock is http://home.att.net/~geoclock/

Hi John,

yes actually it was a friend of mine who told me about the lost planes and
I proposed to him to buy a cheap handscanner. I don't know how many people
they are in his club but estimate 50 to 100 so this should give any
problem for them.

Hi Chip,

I wanted to write field strength proportional square root (power).
If I double the the mass of the earth, gravitational force will double:
I don't have the formula here but I think for two point masses it is
something like

V=- grav-konst*(M)/r
some people put m here, too

Force propto (1/r^2)*M*m

Integrating for a (lets say homogenious) 'real' mass distribution I still
obtain the linear mass dependence.

Now converting to the antenna:
in the NEC formulation, the response of a wire arrangement to a electrical
field at the feedpoint is calculated.

If I double my power, the electric potential at the feedpoint will
increase by square root power.

The response of the wires is linear, so the charges and currents will be
modified in such a manner that the field produced by the wire will
increase by square root (power) to.

Take an infinitesimal current element.
The current is proportional to square root (power).
The vector potential is something like

A proportional (J/r)*exp(-ikr)
J=current
k=2*pi/lambda
r=distance

i='square root of -1'
The H field is rot A (outside the wire at least) proportional J
The E field is rot rot A (same restriction) proportional J.

To me all fields are proportional square root (power) ???

For real antennas just sum up many current elements. You still have the square root (power) law.

By taking the response of the antenna to an external field, you arrive at power delivered to load is proportional H- or E-Field squared (by inverting this confimrs the above law).

The far field is produced by superposition of the fields close to the antenna some how (optical equivalent diffraction).

If the near field did not go by square root (power) but the far field does, wouldn't that mean that my far field radiation pattern becomes power dependent ?
Is NEC totally useless then ?

Hi, Jim

I'm among the people (or maybe I'm alone) who understood the initial
question in the latter sense.
Strictly speaking, my argumentation refers to this case. But if your 80
mtr Dipole is only '0.5 mtrs from resonance', you can probably/hopefully
use the same argumentation. I'm not sure what happens if I have to double
the antenna's length to make it resonant. I think it depends on where the
field strength is measured (a maximum perhaps becomes a minimum then ?).

> If no adjustments are made to the antenna--can we count on near field

> Never mind whether it varies inversely proportionally to R, or R^2...
> Never mind whether it varies linearly at all with respect to power
> delivered to the antenna (though I suspect it probably should)...
If no length changing is done, the field strength is proportional square
root (power), whereever you measure it and this will at least mean maximum
fieldstrength = maximum power radiated .

>
> I suspect that the only precaution we'd have to take to be able to

I assumed that all field indicated is coming to the meter from the
antenna.

I don't like the idea to put a field strength meter in the tree to avoid
measuring rf in the shack, so I tune via swr indicator. In my CB times I

tried once to tune via field strength (meter close to station) and I only
got 'maximum distortion', to me that means that although the square root o
power law is correct for all fields, it might be of limited use for
tuning.

I recommend that you try (in order) 2, 1, 3. I used a booster amp once, and while it worked ok, it badly overloaded the receive when NOT in a fringe area. Having experienced the difference between a magmount "mini whip" and a 7/8 wavelength trunk mount on 2 meters, the difference with a GOOD antenna is dramatic.

NEC isn't "totally useless" -- it's in daily use worldwide, helping to design real antennas that work. The strength of both the near and far fields (volts or amps/meter) are proportional to the square root of the applied power, and NEC reports this. Most people view far field outputs in dBi, which is normalized to the power input, so far field results in dBi do not change as the input power changes.

NEC calculates both the electric and magnetic fields, giving results accurate in both the near and far fields. If you're interested in how it's done, you can find the NEC-2 manual on line at http://members.home.net/nec2/preface.html. The EZNEC demo (free, from http://eznec.com) can be used as an easy way to look at NEC-2 results with simple antennas.

Interesting group called "HFpack" has just formed on eGroups. It is growing very fast. Here is the link:
http://www.egroups.com/group/hfpack

This is the description:
Portable and Handheld HF Transceivers and Antenna systems for backpack operation. Walking and portable operation of HF SSB / CW / Data systems in the field. HF Handhelds. Battery and alternative energy operation of HF systems for amateur, commercial, marine, and other systems. Miniaturization and use of Manpacks, Personpacks, HFpacks, solar charging, lightweight power supplies, ergonomic designs for backpack radios, mounting systems for whip antennas, compact antenna tuning and loading devices, tape antennas, collapsible antennas, handsets, controllers, headsets, microphones, earphones, keyers, paddles. Low power consumption techniques for transmit and receive. Portable RF Amplifiers and maximizing effectiveness of low RF power output transmitters. Expedition radio systems.

The other option is to bring up the Character Map application (in Accessories). You can then search for the character you want. Click on the character, then click on Select, then Copy. The character is now on the clipboard, and you can paste into your main application. Slower, but works fine.

First things first:

How do you propose to keep a Yagi pointed in three dimensions to a
desired heading?

Think about it . . .

I really doubt that there is anyone else with such experience to guide
you.

3329. Looking for recommendations

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-29 03:17:27 UTC
From: David Findlay <nedz@bigpond.com>
Message-ID: <Uu_U5.145790$e5.85780@newsfeeds.bigpond.com>
Source record: 175552
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.space

First, sorry for the cross-post, but this is relevant to both groups and saves me typing this twice.

I am looking for information and recommendations on antennas for space communications. I have read about quad-helix antennas in an old antenna book, and these seem to be exactly what I want. I don't have room for a dish. I would like to know of anyone's experiences using these. Also how are they to build?

I am mainly looking to recieve images from weather sats, and listening to manned spacecraft such as the shuttle and ISS. What size quad-helix should I go for and what bands are most useful? I am going to build on a motor driven alt-az mount that will be guided by computer software.

Any recommendations on these antennas would be appreciated.

David Findlay

Check back issues of QST. There was an article or two sometime in last
two years about using balloons to support antennas. I just checked my
Dec 2000 QST index for 2000 and found no such article, must have been
earlier than 2000.

I'd rather get a butternut myself. I've had the 80-10 hustler and wasn't overly impressed. Sure , you can get out on them, but they seem overly lossy to me. On 40m compared to a 32 ft whip was like a dummy load nearly.
With the excess loss of the hustler 80m resonators, I wouldn't expect 80 to be that great either. I gave the hustler vertical I had away. I'd rather build my own where I can control things, but if I were to spend the money on one, I'd go the butternut. I like the design better. No traps. Also about the radials, both need them. The performance of either one is greatly improved with radials. The radials or radial are half the antenna. If they are missing , you have an incomplete antenna. And your feedline becomes the lower half. Not good. The performance of either one without radials won't be anything to write home about. Judging by my results with the hustler I had, without radials it will be a good dummy load. Or at least compared to a "good" antenna like a 1/4 whip. The shorter the radiator in wavelength, the more critical the ground radial system. MK

><snip>

I used to use a longwire attached to a large kite for SWL. Copper
coated steel welding wire worked pertty well but direction depended on
the wind.

You might try a kite with a 6 or 10 Meter dipole as the vertical
"stick". Or go horizontal if the wind is blowing along the axis you
want to listen/transmit to.

Wonder if Lawnchair Larry took a portable reciever with him?

Imagine the FM DX he could have picked up ;)

Tch Tch Tch. Some of the younger fools are launching nylon monofilaments over the high-copper, and pulling small-diameter wires up from anchored spools .. they do it from far away at nite, and the high-energy plasma is spectacularly bright, and must be loud (squirrels pop the 65A fusible primary links around here, and it sounds like a 105mm shots). Must look like lightning striking the lines. Apparently, pilots are spotting these incidents after nightfall.

What next?

Wonder what the fault current is?

Should we hope the perps don't confuse the spools? Or spark a blaze?

3343. Re: Balloon Supported 160M Vertical Wire

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-30 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <905msb$l1n$1@uranium.btinternet.com>
Source record: 175498

A kite or baloon supporting a sloping wire works wonders on
160m.

A 1/4 wave 130-foot wire requires a very low resistance
ground connection for high efficiency. Not easy to arrange
for a field day.

A nice length is about a halfwave where even a very poor
ground connection provides moderate efficiency but 250 feet
of wire in the air might contravene regulations and be
expensive to erect. A 5/8-wave is perfect, day or night.

So for us ordinary mortals, best length is roughly 3/8-wave,
about 200 feet. It will tune very nicely with a series 140
pF capacitor (300 pF max to make sure for somewhat shorter
lengths).

>above- as far as reducing unwanted noise?

You might look at a bigger and/or better antenna. Try
http://www.ccrane.com and look at their FM car antennas, especially
their big mother trucker's am/fm antenna.

That's not guaranteed to work, but it might be worth a try.

I'm not sure what kind of FM filters you're talking about, unless it's
a filter to reduce engine noise and hash. That might help, but your
basic problem is your station is too far away to lock in on the
receiver, so, in turn, you hear more engine noise or whatever.

Another thing you can do on weak FM stereo stations, is to simply put
your radio in the monoaural mode. That kills your stereo effect, but
often makes the signal easier to lock in. (I'm assuming your radio has
a stereo/mono switch -- it may not.)

3345. Re: hustler 6-btv any good?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-30 00:00:00 UTC
From: Greg Knapp <gknapp@freshrain.org>
Message-ID: <t2ct17erpaha96@corp.supernews.com>
Source record: 175500

I've used the 4BTV and 6BTV and I think they are ok antennas, certainly worth the price.

As far as radials, I read in a DX mag about DXpeditions using chicken wire, so I tried an experiment with mine once in which I put down and hooked up two 25 foot by 18 inch wide strips of plain old chicken wire in an "X" under the 6BTV--best ground system I ever used--I was really shocked! But I don't argue with actual experience! So I left it for about a year. Then I decided to see if I could improve the performance by adding a normal radial system. I added several radials for 20, 40, and 80, but couldn't notice any improvement.

Only problem with chicken wire is that you should replace it frequently, perhaps every year or two, long before it embeds into the ground because as it disintegrates it will leave you with a mess of sharp ends and something hard to pull up. Mine is in a pasture so it doesn't matter. You might use the same idea, but much shorter strips to fit your room. Of course, if the area is frequently traveled by guests, remember, it doesn't look very pleasing to anyone but a ham!

The principle is that if you don't have a lot of room, use lots of radials to blanket the ground in the area you do have.

As far as a counterpoise (I assume you mean you are going to elevate the 6BTV), you should have a bare minimum of one resonant for each of the 6 bands, as they form the other half of the semi-vertical dipole for that band.

If you decide to use a balloon, please strongly weigh the risks of it escaping because of a broken line. I've wanted to use a balloon, but haven't used one because I live in a heavily traveled flight zone (commercial jet pattern for San Jose is about 3000 feet above my home). I'd hate to think the problems--or liability--a loose balloon might cause!

Hi All,

I need some help with a coaxial type collinear antenna. I used to have the diagrams to knock one of these up, but I've lost them. If anyone can help with designs for 70cm or 23cm then that would be great. I have need for a vertical antenna with gain for 2320MHz and by scaling one of these antennas for the band maybe this will be a suitable antenna for vertical polarisation.

Email direct please to AdamORY@ntlworld.com

With thanks in advance for your time and effort.

I'll second that. I have a Gap antenna which is supposed to handle 10-80 meters. It's mounted on a simple tv-antenna pole sunk in concrete and bolted to the side of the roof, with the antenna only up a little higher so it won't have to be guyed. I use it mainly on 10 and 20 meters with no problem. It tunes fine with my Kenwood TS-940SAT internal tuner down through 40 meters, though I haven't operated 40 much. I can't get it to find a match at all on 80 meters. I've tried an external MFJ-989 tuner, which is a piece of sh*t and won't tune on any band.

So, I'd easily recommend a Gap for 40-10, but if you're wanting to do 80 or lower, go with something else. I'm seriously considering a trap dipole.

WolfgangS (schliess@gmx.de) wrote:
: Hi !
: I want to calculate the L component of a Magnetic loop.
: Is this right ???

: r=radius
: w=width of the loop lipe

: L=12.57*r*log(2*r/w)+0.08

: (Magnetic) Loop
: N=1, r=50cm , w=1 cm
: L= 2.8944 uH

: (Magnetic) Loop
: N=1, r=50cm , w=4 cm
: L= 2.031 uH ?!?!?!!!??!

: Can is be when the w increases then L component decreases ?!?!?

The external DC inductance of a thin circular loop is calculated in many texts. In the one in front of me, J.D. Jackson's Classic Electrodynamics, it is given as a problem at the end of a chapter 5. In microhenries the result is
L(microH) = 0.1 4 pi a [ln(8a/b)-2]
where a is the radius of the loop in cm and b is the radius of the wire in cm. the factor 0.1 is the conversion factor between electromagnetic and SI units. This is identical to the formula you wrote in your first post, and identical to the formula that Reg wrote (if I assume that his 2.451 is an approximation to 2-ln(2/pi) = 2.4516...). For your first formula the lengths need to be in meters, and the log is base 10 rather than the natural log above (your factor of 2.3 is ln(10) = 2.302...). At true DC, there is current throughout the cross section of the wire, and you may find formulas that have -7/4 instead of the -2 above. These include the inductance from the magnetic field in the wire -- the so-called internal inductance. At rf the skin effect makes this negligible. As Reg mentions, these DC approximations will only be reasonable if the loop is small and the wire thin.

As you make the wire larger, to a first approximation, the magnetic field outside the wire is the same as it was before at the same distance from the wire. Now however, you have excluded the field from the region between the radius of the original wire and the larger wire. The field energy in this volume no longer contributes to the inductance, and the inductance is smaller.

Cecil--I think he wants to increase the transmit range so he should tilt them forward like the truckers so they can talk down the road farther. If the station is behind him, he could use motorized mounts and tilt them back for gain that way. Maybe tilt one forward and one backwards and vary the phase. I know I am about 4 months early with this!

It is nice to see a reasonable implementation of transient analysis once in a while!!!! It is also nice to see that proper emphasis has been put onto the fact that whatever happens inside of the source is not the same as what happens on the line. For those whom really like equations, you can describe your source in a practical AC circuit as follows:

Vs=Acos(wt)--where 'w' stands in for the proper lower-case omega.
In the DC circuit (DC within the time constant of the 'circuit') representation that is used in many instances the source is:
Vs=A(sqrt(2)). A is a constant which represents the RMS voltage.
Now, when a DC Vs is applied to an open circuit, we can argue whether or not the transient current flow inside the elements of the open circuit has a value or not to high heaven (it does, by the way..... represented by: I(t) = Ishort *e^(-at), where a is 1 over the time constant--1/'tau'--assuming that the circuit is critcally damped), but it will not affect the steady-state AC response beyond approximately five time constants (5*'tau'). This is because the un-terminated feedline acts like a capacitance to a DC transient signal. How a feedline reacts to a true AC circuit (one that is AC INSIDE OF FIVE TIME CONSTANTS--& one where AC is represented in a sinusodial waveform) has very little to do with the DC response of an un-terminated feedline--certianly not enough to be used as a argument against reflected energy in a feedline.

(I think that everyone here knows what to do the above information for other solutions..., so I'll let them drop for now.)

Also, TDR uses a half-wave AC-like waveform. Therefore, it can prove reflected energy, but it has nothing to do with DC transient response within five time constants (at least so far as we mortals care to solve the differential equations for....). Thus, any argument which shows that TDR works does not work for a DC transient response argument (under nearly all cases.....) & vice-versa.

In any case, reflected energy is easily proven to exist by a simple high-school physics experiment. Attach two lengths (about 10 feet) of different mass-per-length ropes (different "impedance" ropes....) together. Tie one end to a door knob. Move the free end in a sinusodial motion as if you were to be jumping rope with somebody. Feel the reflected energy as it comes back to your hand & your body attempts to absorb it. Reflected energy exists. Impedance exists.

Does anybody dare to attempt to disprove that?

I need a 144/440 dualband mobile antenna. Assuming the glass on my 98 Honda Accord coupe isn't the UV metalized kind, how close to the embedded heater wires in the rear can I get with a thru-glass Larsen? Will it hurt if the edge of the mount is right next to one of these wires as long as it isn't underneath it?

Or....if I don't go with the thru-glass Larsen and opt of an NMO mount with a 3/4" hole in the roof, which one would you recommend? Mind you, I don't want anything too long (I'm already sporting an HS-1500 screwdriver), preferably under 36" would be nice.

Any ideas?

Thanks,
David, K4ZZR

Some top-end TV preamps have FM traps built in to keep strong FM broadcast stations from causing IMD problems with TV reception. Cheaper ones may not, and can provide "flat" response (which means you may hear a few TV sync buzzes mixed in with your FM).

If your TV antenna is a LPA (which most are), it might provide good FM reception. On the other hand, it--too--might have an FM trap built in on a PC board at the feedpoint. Sometimes these filters can be switched on or off (Wineguard used to offer this feature). See the literature with your antenna and pre-amp so you'll know exactly what you are working with.

Hope that helps.

Bill,
I don't see why a 'current' balun wouldn't work. As Cecil said, changing feed line length can change things so that the tuner is 'happier' with it. I would suggest that the coax going out to the balun be as short as possible. The usual recomendation is no more than 12 feet. A couple of feet one way or the other shouldn't make a ~lot~ of difference, but keep it short...

Take some good advice and don't bother with modeling that antenna J.C., as MOM (NEC) modeling assumptions do not include conditions where elements have become critically coupled.

Hi Cecil,

This says much, but answers nothing in regard to my comments to
Edward.

I have noted for years that mag mounts do indeed work, so do air
cooled resistors - either work to some degree.

As we are offering a newbie solutions to a difficult (apartment)
situation, it behooves us to not simply offer marginal answers where
simple solutions could easily resolve his problems. A mag mount may
indeed take care of it, but as you note by your proviso:
>They work well with the
>capacitively coupled ground plane and don't work well without it.
introduces the issue of what constitutes a good ground.

I am assuming that a metal disk, 1/2WL in diameter, would be the
minimum adequately functional magnetically coupled ground plane.
At VHF/UHF frequencies, metal desks, metal tables, and metal filing
cabinets are usually that large or larger.

Robert,

It is possible that you could bend the dipole around the balloon in a open loop similar to an onmidirectional H-polarized - or perhaps like a circular polarized - FM broadcast antenna.

However there is one conundrum to consider; as the height above average terrain increases so will the ERP. However the feedline losses will increase with its length.

> is that way?

It's a property of the font, which a program has access to. For example, some of the outputs in EZNEC, like the tabular far field output, require a fixed font to be displayed properly. So when you open the "Set Font" dialog in this window, the program gives you only the fixed width fonts on your system to choose from. The property is surely embedded in the font file in some manner.

>begin to fry yourself and family members.

I think "fry" is a bit excessive. But hams should comply with the regs.

There are a lot of factors that can enter into RF safety. The transmit power is one, but that can be adjusted by feed-line losses, operating modes and duty factors. For a typical 50-watt FM operation, a ham might operate for only very short periods.

A good rule of thumb for the required distance in feet on VHF is:

D = 1.047 * sqrt(P*G) where P is the *average* power delivered to the antenna in watts and G is the *numerical* gain of the antenna in dBi. An antenna of 3 dBi gain has a numerical gain of 2. If the antenna's gain is specified in dBd, add 2.15 dB to the gain to obtain dBi. I usually round it down to sqrt(P*G).

For info on RF safety, see:

http://www.arrl.org/tis/info/rfexpose.html

Most of them, actually. There is considerable capacitance between the mount
and the metal surface. The only time I have had a problem is with my HF mag
mount on 40 meters and below; there was insufficient capacitance to get a good
"connection."

As Roy knows, I am one of those that refuse to put his credit card numbers on the Internet. While the law might limit the monetary loss, the hassle of cleaning up the mess if security is breached somehow, scares me to death. I recall recent news of none other than Western Union contacting hundreds of clients to ask them to cancel their credit cards because their numbers had been stolen from WU's "secure" system.

That said, I can give a personal example of just what Roy is talking about when he mentions turning over your card to the gas pump jockey. Only in this case, my wife went to the rural Mom and Pop grocery to get some fuel. The credit card reader on the pump was inoperative so she was required to leave the card inside the store while she pumped the gas.

When I reconciled the monthly statement, I noted an extra $20 charge with the same merchant number and a transaction number one digit removed from the gas purchase. Apparently a crooked clerk pocketed the twenty and used the charge slip to make her cash register balance. A call to the credit card company got the charged removed, but only by maintaining constant vigilance and meticulous record keeping can one be sure he isn't getting ripped off.

I suppose my tale makes Roy's point but I remain in the minority camp on this issue.

At least as important at this frequency as getting the lengths right is making the connections with near zero length wires. I think a pretty good job can be done with semi-rigid coax, swapping phase as is done with collinear Franklin type antennas. Even so, the significant impedance bumps at the junctions might be bad enough to throw things off. By all means give it a try, but do pay careful attention to the connections.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A284218.E824F8F3@eznec.com>
Source record: 175336

There's nothing magic about "critical" coupling, and no assumptions made by NEC which make it unable to model antennas with this claimed mystical feature. Claims that NEC is unable to model them is promoted pretty much solely by antenna vendors who've found that NEC's results (which correspond well with known theory) contradict their unsupported claims of impossibly good performance.(*) I suspect Anon is one of these. Unlike Anon, I'm willing to attach my name to what I say.

Roy Lewallen, W7EL

(*) Some time back I publicly offered one of these vendors, on this newsgroup, to pay the cost of a professional antenna range test if its results showed the performance he was claiming. He didn't accept. Apparently professional antenna ranges also make assumptions that make them incapable of demonstrating the true, miraculous performance of these antennas.

Not really normal. I've got one of those and mine tunes just about
anything. Actually, I don't think I've ever not been able to tune
something with it. The only gripe I have with it is the somewhat flimsy
roller coil. I've had to adjust it to keep it rolling tight. MK

It can happen. Try to keep the wires at right angles if possible. I'm curious...How high is your current 40 antenna? If you are not high in the air, it's likely your pattern quite omni directional. On most dipoles in the real world at low heights, you may have more performance broadside than you think. If the new dipole wins it will likely be because of better perfomance due to being a non trap antenna rather than direction. You will need to get it pretty high to see any nulls off the end. MK

Newbie asks about working from within an apartment with 50 watts on 2M/440.

50 watts is WAY too much within the confines of an apartment if you don't want irate neighbors coming after you with tar and feathers. Also, that amount of power in close proximity to your eyes, brain and other soft tissues would do a world of hurt to you in quick order.

Five watts is more than sufficient even to access repeaters nearby. On a recent trip to Denver I used 3 watts and a 5/8 rubber dummy load to access several repeaters on mountain tops 15-25 miles away.

Buy a couple of SO-239 flange chassis mount connectors and build "droopy drawer" antennas for 2M and 440. No. 14 gauge solid copper wire for the verticals and radials. Vertical solders to the cup on the back side of the SO-239 and the radials solder to the four holes in the flange. Use a short length of RG-58 to PL-259 connector and you're in business. Just don't jerk on the coax as the vertical may pop out of its cup if not soldered in properly. [somewhere here I've got a cutting length chart for Antenna Specialist scanner antennas I used to put together for sale to fire departments/EMTs. Check to see if someone in your area has any of those or re-read the antenna compendiums for info on the 1/4 wave ground plane antenna. Form a small loop in the vertical and you can hang it from the ceiling on a swag lamp hook.

Mag mount antennas rely on the body of the vehicle they mount on top of to act as the counterpoise for the radiated signal. Tabletops won't cut it. At least put it on top of a fridge or a top opening freezer.

I have read *hours* worth of "Apartment Antenna" threads from the various usenet groups via deja.com. I have one question for the group:

I'm new to all of this so please be kind.

Can I simply stick a oh, say a little Cushcraft AR-270 in the corner of my apartment? I would like to work 2M/440 on a Kenwood TM-D700A from inside. I can grab quite a few repeaters in my area from inside with my HT and a Comet SMA-24. What about a 20'' mag mount on a table? Would that work OK?? Is 50w too much to push out in a setup like this etc??

Thanks in advance.

I'm not specifically familiar with any of that equipment but the bottom line is that it all depends on how far you are from the machines you'd like to hit and the terrain and close-in obstacles between you and the machines. I can hit a couple nearby machines from anywhere inside my apt with just an HT with a rubber duckie. Right off a magmount antenna depends on the sheet metal of a vehicle to serve as a gound plane to opererate properly so forget the mag mount antenna. Any antenna designed to be installed outdoors on a tower or pole will include both the radiator and the ground system (radials or coaxial sleeve) and will work properly. A Ringo, one of the Larsons hung upside down from the ceiling, etc. Personally, I'd homebrew dipoles and tape 'em to a window. As far as power goes, check the manufacturer's specs.

Hi TJP,

The problem you are going to encounter is RF exposure. At 50 watts, you will need to give the antenna a minimum of six feet clearance, otherwise you begin to fry yourself and family members.

At five watts, or maybe even 10 I think you might be OK. I had a MFJ portable J-Pole that I used when I lived in an apartment, hung it up next to a window, hooked it to my five watt HT and away I went.

At 50 watts though, you really should get the antenna outside. Maybe you can put it on a balcony while you use it, then take it down afterward? That would be easy to do with a mag mount, and you could be inside with the antenna outside and have a wall between you and the 'tenna.

Many years ago, when I lived in an apartment for a short while, I ran a horizontal 5 element Cushcraft 2/440 yagi suspended about 6" from the ceiling with an extension from the existing ceiling light tubular rod that held the cover on. You can buy this rod in various lengths from most hardware stores, etc.

Simply unscrew the cover, remove the short 6" rod, replace it with about 15" of new rod. Then replace the light "bowl" and use a nut instead of the knurled button to hold it in place. This leaves about 8-9" of rod to mount the antenna to. I mounted it by drilling a 1/2" hole through the antenna boom, passing the rod through the boom, and securing it with the original knurled button from the light fixture.

The antenna weighed only a few pounds, and it never presented any problems from this type of mounting. Turn it via the "armstrong" method. I ran a 100 watt SSB rig through it and it worked very well. If you happen to have one of those hanging chain lights, you can even run the coax back down the wall using the existing chain hooks.

When the time comes to move, simply replace the original fixture rod, put the light cover back on, and nobody will ever know the difference.

>Perhaps your problems lie elsewhere?

I'm assuming I have a bad one with an internal problem somewhere. I opened it up, and I'm not very impressed with the quality inside of it. I did some checking, but everything seems ok, just find it doesn't seem to want to tune well at all. This is my second MFJ tuner, the first was a Versatronic II. It also failed to work adequately, but I suspect in that case it wasn't the tuner's fault, since I had a very compromised dipole arrangement in the attic of a duplex. But with the 989C, I can't get it to tune to an adequate swr on any band, including ones my internal tuner on the TS-940 has no problems with. That's the reason I think the MFJ is trash.

>
> Roy Lewallen, W7EL
>
Hi Roy,

totally agreed. There are some people around who say that far fields
follow the 'square root law' and near fields don't. According to my
understanding of the Maxwell equation ALL fields should follo the square
root law.

I did not want to say that NEC is useless, I only wanted to say that it
would be useless if the near fields did not behave like this.
According to my memory the theory part of the manual (I think it was part
one of the manual) starts with the vector potential mentioned in my
posting and evaluates the fields in a similar manner as I did (the 'art'
is to make currents and fields 'self consistent', it's no real task to
calculate the fields given the currents/charges).

NEC (used in the form of NEC2d here) is an excellent tool to me. I've done
a lot of modelling with NEC and almost always obtained results close to my
'intuition'; since last friday I cannot say this about the MININEC based
program I use here, but this may be due to bad formulation of the problem.
The only weakness I have noticed is modelling very small
loops (close to ground you can produce negative feedpoint resistance ?).
I think there is some 'improved loop code' developed but I don't know if
it's available 'to the public'.

Guess I would by the EZNEC version for windows if there were a distributor
in here in germany and the price were not higher then 200 DM. I think is's
advertised in QST for 89 Dollars so the second condition would probably
within reach. I'm convinced that EZNEC is worth every Dollar it costs, but

don't like the idea to send credit card numbers via the internet. Maybe
you find a way to sell it germany, too.

I downloaded the font and installed it. Now my zero's are slashed!

Unfortunately, I have lost the ability to distinguish between

0 and ï¿½

They are exactly the same! I will never be able to read Norwegian
again! However, I couldn't read Norwegian before, so the impact
will probably be minimal.

Interestingly, some of the other programs I run that insist on using
fixed-width fonts, notably Not-GNU, don't recognize the font as having
that characteristic. I wonder if that's a Windows setup thing or is
there a bit set in the font file itself that tells everybody it is
is that way?

Chip, This NG is the Amazon.Com_from_Hell_and_Damnation. It reads your cookies and snidely tells you which books you DON'T want to read, the books ordered by people with whom you have violent disagreements and the addresses of mental health facilities you should visit at first opportunity.

;-) <----- (note smiley-face)

FWIW, quite a while back a NG participant alerted us to the opportunity to buy the old, gone-out-of-print edition of Jasik & Johnson's "Antenna Engineering Handbook" for $5.00 from Edward Hamilton, Bookseller. The savings from that transaction paid for 6 months of my ISP subscription.

Book and software for-sale postings seem to me to be appropriate to the intellectual pursuits of this NG. Ordinary antenna for-sale or for-auction postings might find a better venue in the r.r.a.swap NG, if only to avoid the inevitable, acidic follow-ups denigrating the offered antenna as an efficient radiator of electromagnetic waves.

I remember an article in german cqDL magazine about one of the GAP antenna. It was not the 10 to 80 mtrs Gap but the one 80 to 20 or so (was it called 'Challenger' ?). The OM also tried to use a MFJ tuner with this antenna and said it was not possible to tune on some bands. I think it was due to a capacitor at the output, will try to find the article at the weekend.

I need to put another antenna in my back yard that will favor East and West on 40M. It will be close to my 80-40-30M trap inv-vee that runs along a nearly East-West line. The new antenna will probably be a dipole running perpendicular to the East leg of the inv-vee and a few feet above it. My concern is that the close proximity of these antennas will result in interaction and who knows what for a pattern. I have tried to model various arrangements but my model is probably over simplified. Any thoughts on this would be appreciated.

I'm putting up an inverted v on top of my 2 story roof. The metal mast attached to the side of the roof is 30 feet from the ground to the apex. The width of my roof is approx 30 feet and the roof height is 16 feet.
This makes the apex angle approx 90 degrees.
Using the antenna design program EZNEC to compute the wire lengths for 14.03 mhz, I get 17.5 feet for each side of the dipole rather than the expected 16.5 feet.
Does this seem OK?

In my second floor condo I use a Cushcraft 270 standing in a corner
hooked up to the Yaesu 5100 putting out 50w. In the bedroom I have
a RS HTX-202 on a 13v power supply hooked to a MFJ roll up J pole
putting out 5w. In the living room I have a Kenwood TX-28A with
a hotrod antenna also on 13v and putting out 5w. All work well into
local repeaters. The Kenwood will not make the repeater without the
hotrod on it's internal battery. With the hotrod it will when the
battery is fresh. On 13v it will make it with the rubber duck.
I bought a three element beam (MFJ) but the J pole works better.
The mag mount would be better on top of the fridge or some other
metal object. The RS HTX-212 in my truck with a mag mount works
well on the cab but wouldn't work on the fiberglass camper shell
even if it would stick. 8-)
I've not noticed any problems with 50w but 5 is usually enough.
Maybe the green pin feathers I've started to sprout may be a
side effect?
I would put the antenna as far away from your operating position
as possible. You could poke a hole in the ceiling of a closet and
stuff the 270 up into the attic. Unless there is another apartment
above yours. Might cause some hassles if so.

Now I don't remember the exact details but I remember a tale from my youth (1970s). Apparently the Wimbledon and District Amateur Radio Society, some years previously, had used a gas-filled weather balloon to raise an antenna during a field day event. The balloon broke free of its mooring and was lost. Next day one of the London evening papers reported the discovery of an unidentified balloon which had landed somewhere in West London. I don't think the W&DARS and the balloon were ever reunited.

Let this be lesson to you! Sounds like a lot of fun to me!

Anyone know the full story?

Oh, no! It's happening to you, too. Mrs. Malaprop said, "I am sorry to say, Sir Anthony, that my affluence over my niece is very small." Later, "Well, Sir Anthony, since you desire it, we will not anticipate the past! - so mind, young people - our retrospection will be all to the future." I think this newsgroup needs the services of a priest to exorcise the old broad's spirit. (I almost wrote "exercise.") Is there a priest in the group, or even a guru?

Hi Troyce,

You may want to consider that your difficulties might have been due to
common mode currents rather than poor equipment. Your hint of a
> very compromised dipole arrangement in the attic
would make this a near certainty - especially if you did not
sufficiently decouple your line from your antenna through a current
Balun.

Got a balcony with a metal railing? That'd work. Mag mount atop a metal filing cabinet works too, just remember that any metal near the antenna (discounting the metal filing cabinet) will detune it.

Don't spray 50W of RF at yourself and the family at close distance. Use 5W.

If cable TVI becomes a problem, esp. on cable channels 18 or 19.... move the antenna.

Good luck.

Mike N5MJ

I use the Gap Voyager and have had pretty good all around results with it. On 160, it beats out my full size dipole over about 1,000 miles--working KH2, KH6, etc., but gets trounced on local (up to 500 miles) stuff--which is to be expected; on 80, it allows me to run the east coast while my full size dipole allows me to only hear them--the dipole is better close in; on 40, it is roughly equal to my 40 meter full size dipole and ground mounted 6btv with radials...sometimes the dipole wins, sometimes the voyager wins; on 20, its about equal to my full size dipole. All antennas are in the back pasture, so buildings/trees etc. are not a factor. In tons of A/B tests, I certainly have found no evidence for the accusation that it is an inferior antenna or acts like a "dummy load." But, your mileage may differ.

Also, it has the wonderful convenience of low SWR across large portions of the bands, something valuable to me as I enjoy operating all modes all frequencies--and my rig loves it! (Yes, I know dummy loads have a perfect 1.1 to 1 across all bands...but they don't get out like the GAP!).

Yes, let's be frank--there are better antennas--like the 3 el 75 meter full-size monster beam on a 150 foot tower I heard this morning working stuff I could not hear--but the guy moaned he couldn't QSY more than 10 khz because of the narrow bandwidth. Hey, if working DX in one speck of 75 is your thing, go the $20,000 monster antenna, I am sure you will be happy...but I can happily work lots of DX on both CW and SSB, and work both 3.501, 3.795, and 3.995 without problems! A ratio of 50/1 bandwidth over the "monster." It just depends whether you want a well-rounded do-everything antenna or not.

I have not had an opportunity to compare it with the butternuts or R7's, so have no idea how it compares to those.

As far as durability, my GAP Voyager has been up for about 5 years and has never given me any problem at all. For those of you who are "right brainers," think of it as a 46 foot work of art that also doubles as a ham antenna!

73,

Greg, N6GK

JB,
It will naturally affect the 'tune' of both antennas to some
extent. With the second antenna being perpendicular to the other,
there should be less affect than if they were parallel. Depending
on the height, neither one probably has much of a pattern anyway.

CB antennas are usually fiberglass or flexible metal whips.
They tilt the antennas forward so that when they are at
highway speeds the antennas are near vertical.

>There is a capacitive coupling to ground.

Hi Edward,

This goes without saying, but is this capacitive coupling from the
radiator, or from the feed? Or in other words is this capacitor
across the feed or in series?

As it stands, without a direct connection, yes there is certainly a
capacitive load added due to the proximity of this sheet of metal, and
as that sheet of metal must then serve as a circuit element, it
necessarily needs to conduct as part of a network (that is through
ohmic, metal connections to satisfy that half of the circuit). Thus
my question, is there a direct, close metallic connection, or are
these currents in the capacitance forced to find the long way back to
the source?

A sheet of metal in the vicinity of an antenna is not a guarantor of
fulfilling the function of a ground plane. If this plane is large
enough (on the order of several many wavelengths, 10 typically) then
it can serve as an improvement to low angle radiation, but that is a
far field phenomenon and not a function of a ground plane per sï¿½.

There are far too many reports in this group of improved performance
where radiators' feedpoints are tied directly to the sheet metal when
they replace thru-glass or mag mounts.

Well, assuming he uses solid Teflon dielectric semi-rigid line, which
should be a very reasonable way to do it, each section will be around
8.9 centimeters (3.5 inches) long. It will be important to measure and
construct accurately, but then that's true of pretty much everything you
do at that frequency anyway. (I sent him a writeup about how to do it,
via email.)

Cheers,
Tom

If it's perpendicular, +/- a few degrees, coupling will me almost nil.
Go for it.

The way I understand, it's a capacitive coupling to ground at the feed point.

I've found a way to sell it in Germany -- several, in fact. I probably sell more programs to Germany than any other country outside the U.S. And visitors from Germany to my web site consistently outnumber those from any other country except the U.S.

Communication with the secure server used for web credit card orders is encrypted by the site and your web browser, and I've never received a report of theft or fraud due to purchase from my web site. U.S. customers are limited by federal law to a maximum liability of $50 if their credit card is stolen. (I have no idea what protection is offered in other countries.) Nevertheless, a surprising number of people even in the U.S. are willing to give their cards to a sales clerk or gas pump jockey but aren't willing to purchase via a secure server on the Internet. I don't understand this, but it's o.k. with me.

Anyone who doesn't want to purchase via the internet can order by phone, fax, or mail. All necessary information is at http://eznec.com/ordering.htm. International CD-ROM orders are sent by air mail. Typical delivery time is one week to most parts of the world. A very sizable fraction of my sales are to other countries.

Credit card orders are billed in U.S. dollars (required by my bank), which customers see on their bills in their local currency. Most credit card companies give a better exchange rate for these transactions than you'll get any other way. But if you prefer, you can purchase and send a U.S. dollar check. This is invariably more expensive than using a credit card. Occasionally I receive U.S. currency from a foreign country, sent by registered mail. I don't recommend this, but haven't gotten any reports of money being lost this way. I don't accept direct wire funds transfers for the standard version, because at least two banks are involved, each charging a substantial fee.

If I had a distributor in Germany, he would have to be paid for his time and trouble, and would have to collect from you the sizable taxes you have there. Disks would either have to be sent there in bulk, with duty being paid, or manufactured there. Because of the smaller quantities, manufacturing cost would be higher if produced there than here. My share

of the DM collected by the distributor would have to be converted to dollars with the usual currency conversion losses (considerably greater than losses from a credit card sale). The result would be that the program would cost a lot more. And I would have a lot of extra work and get less from each sale. Other than saving the typical one week transit time, what would be the advantage to the customer to have a German distributor?

We are more and more getting to be an international community, and can all benefit if we don't consider international borders to be an obstacle to commerce, but instead figure out ways to make them transparent.

This seems like a pretty commercial posting, but nearly all the information applies to any international web sales and purchasing, which are becoming increasingly common. I hope readers find it informative.

All of the VHF/UHF mag mounts that I have tried make an adequate
capacitive RF electrical connection. They work well with the
capacitively coupled ground plane and don't work well without it.

A mag mount antenna for 2m/70cm will fork fine. I used one 2 years ago on an ironing board setup in front of a window on a 9th floor dorm room at the local university. The antenna worked fine with a 50 watt mobile unit at full power. Used this for some contacts while at the Dayton Hamvention. Everyone we talked to got a good laugh about what we using, but it sure did work.

Last year used a 5/8 wave 2m/6m mag mount stuck up side down on the drop ceiling panel supports as a ground plane. That worked fine, after a little tuning, with a new IC-706G a friend got at the Dayton Hamvention last year. Worked some 2m, and 6m stations. with that setup too. The 6m tuning was touchy however, got with in 6 to 10 feet of the antenna, and the SWR went to pot.

> etc. Personally, I'd homebrew dipoles and tape 'em to a window. As far as
> power goes, check the manufacturer's specs.

I have used a Comet dual band antenna in the corner of my ground floor apartment for the past 2 years just fine. They don't make the exact model I have any more, but the closest thing to it is the Z780 (4.5 dbi on 2m, 7.5 dbi on 70cm). Make up a simple mount to screw it in to, and add a few 20 inch radials around the base, and you are done. I also have a homebrewed 2m turnstile in the other corner for 2m SSB, and a 1/2 WL 6m loop hanging from the front room ceiling for 6m SSB. Most of the time I never have to run more that 10 watts to get in to repeaters 10 to 15 mile away. So far I have found any type of 6m antenna is touchy to tune inside of the apartment. The wavelength is so long that the antenna "couples" in to anything close by like walls, floors, and ceilings. The 2m and 70cm antennas are fine so long as you keep them about a foot away from the walls, water pipes etc.

What you have to watch out for with apartment hamming is:

1. Keep the antennas as far away as you can from the walls where the other renters have their TV's, radios, computers, etc

2. The vertical antennas may give real bad SWR readings if they are located near water pipes in the walls, and electrical wire runs.

3. If your building has a steel structure, aluminum siding, and or foil covered insulation in the walls. Now you need to think about window antennas or sneaking one outside some place.

4. Power level. Keep it down during the day, and early evening. I don't seem to have problems running higher power late at night because most people are in bed anyway.

5. Check your home electronics. Buy or use filters on your ham gear if the output is not clean enough where your home electronics are picking up harmonics from a 10 to 15 watt signal about 10 feet away.

Interesting scatological comment of the MFJ 989C, Troyce.

Curious, but I use one on all bands and have done so for over 3 years
now with excellent results. I have 4 different antennas that I use with
the MFJ.

Perhaps your problems lie elsewhere?

Might make a whale of a sloping dipole on 160.

Actually it only takes a light breeze for a big kite to lift a lot of
weight.

Make one of those coax antennas where the inner conductor makes one half a
dipole and the braid is folded back over the jacket to make the other half
Let it hang vertically from the kite. It wouldn't take much to get a half
wave vertical dipole a wavelength or two up. Well, except for a *lot* of
horizontal space to keep clear of power lines.

Now, how long would it take a person to strip the jacket and roll back that
much braid??

Father Knows Best
2000 Darwin Award Winner
Confirmed True by Darwin
This is a classic Darwin. The man will no longer reproduce, and his son obviously had better genes for survival than his father-his mother's contribution, plus the more robust half of his father's genes. Although a man who could inspire such rage in a child is not a sympathetic figure, it is unfortunate that his son was traumatized.

(13 March 2000, New Jersey) It started out like a scene from The Brady Bunch. Andrew and his fianc&#65533;e were living together with his three children and her three children in Dover Township, when an argument over chocolate cake icing erupted.

Andrew accused his ten-year-old son of taking the missing container, and the two became embroiled in a heated disagreement. Andrew took the boy out to the garage for a private discussion, and there the conversation became even more emotional. Then the man made his fatal mistake.

He handed a five-inch kitchen knife to his angry son, and challenged the boy to stab him if he hated him so much. The boy put the knife down, but Andrew picked it up and placed it in his hand again. In the heat of the moment the outraged boy took him up on the offer and plunged the knife into his chest. The deadly blow happened so fast that no one could stop it.

Andrew was pronounced dead at Community Medical Center. His last words were "Would you believe the kid did that?"

The fourth grader, charged with manslaughter and illegal possession of a weapon, faces up to three years imprisonment. But Ocean County prosecutor E. David Millard said it was unlikely that he would serve jail time, as the boy had been provoked.

I have tuned antennas for quite a while, but have never tuned a dual band.
I have my 2m down to 1.2:1 but my 70cm is 1.7:1. When I get my 70cm down,
then my 2m goes through the roof.
What am I doing wrong.
The antenna is mounted on the trunk lip, NMO mount, has a base coil and a
load half way up the whip.

No need to worry about a 1.7:1 on a mobile. SWR means nothing until it
causes the transmitter to cut back on your power.

SWR seems to be a holy grail, a properly resonated 1/4 antenna on 70cm will
have an impedance of 25 ohms causing a 2:1 SWR. Coax losses etc will cause
the transmitter to see something less.
What you are seeing is normal.

tjp <tjp@pobox.invalid>
shared these priceless pearls of wisdom:

From long experience...

1. Do *NOT* advertise with an external antenna who is balling up the TV picture on that 40 year old BW TV with a cardboard shield in the next door apartment. Keep a low profile or you'll have them pounding on your door every time the picture urps from ANY source. (Unless, of course, the TV is owned by that titsy blonde that you'd do ANYTHING to meet {;-))

2. The magmount on the fridge or the filing cabinet is by far the best solution for local operation. You aren't going to get DXCC from inside an apartment without a hell of a lot of gyrations that you really don't want to do. Besides that magmount can be used as a mobile antenna if you want to go on the road.

Try a Triangle/Loop antenna. They're directional, don't require as much height, have more gain, and are quieter than dipoles. Best of luck.

Source record: 175272

Several months ago, I had a couple of people asking for this information. Well, I know most of you have probably seen it and we're a little late in adding it but, if you're interested in one of the FM frequencies that'll soon be coming up for bid, the information pertaining to them is available at http://www.MonsterFM.com/engineering/rape.html . Unfortunately, I'm sure that you'll soon realize (by looking at the "Minimum Opening Bid" and "Upfront Payment" amounts) that this is just another way that our beloved government is making absolutely sure that each and every citizen can afford to reach into their pocket and compete with the "big-boys". (There's a bit of sarcasm in this post, somewhere. I'll leave it to you to find it.) There's no way *these* prices could possibly be geared toward keeping "big business" in control of the nations airwaves. But, go ahead and take a look. It's worth it to see the proof "in writing"...
In all honesty, there *are* a few FM allocations affordable to the average "John Doe"... As long as he'd be willing to relocate to the Nevada, Arizona, New Mexico or Utah "Emptiness" and serve an audience of 23.

Subject: [E-Layer] I Really Need Help

A year ago I helped F. DeAquino Design the SysG experiment at his university in Brazil. It was successful Jan 2000 and posted on the Los Alamos bulletin board.

See:
http://jnaudin.free.fr./systemg/html/gravelf.htm

http://jnaudin.free.fr./systemg/index.html

http://www.elo.com.br/~deaquino/

I have been trying to design an ELF antenna to radiate sufficient power density for an application I am working with. Currently I am struggling with two issues. Maxwell's equation for antenna element wave propagation not in free space (i.e. conductivity > 0 and relativity permeability > 1) gives an imaginary value (square root of -1) for a surrounding medium of diamagnetic Bismuth with permeability of ~-2. How is this interpreted? In addition, an uninsulated copper element surrounded by high conductivity mu metel (78% Ni and remainder mostly Fe) says displacement current is negligible. With no displacement current can the element still radiate assuming signal attenuation due to conduction is excessive? Does the antenna need to be match? If so then at one milliHz (yes, 0.001HZ) a gyrator circuit can emulate a billion Farad capacitor to cancel reactance.

Best Regards-
Steve Burns

What is it?
-----------

E-Layer is an unmoderated mailing list, informally dubbed "The
University of Propagation", focused on the study and discussion of
HF Amateur Radio propagation and related geo-solar topics.

What sort of traffic appears there?
-----------------------------------

The discussion list does not deal much with day-to-day events or
forecasts, but rather on the underlying concepts. Thus you will
see little of things like next weeks forecast which are well
covered by other means, but rather you will see theoretical and
practical discussion of propagation matters.

For some examples of the traffic, go to our public message archives at

http://www.egroups.com/list/e-layer/

Start by browsing through the "Prop 101" messages from Bob Brown.

Maybe, maybe not. Back in '89-'90 I made DXCC from an apartment with
no external antennas at all. I had a couple of bent dipoles in the
attic, which were actually easier to install than stringing up dipoles
outdoors. Worked great, took about 18 months starting from scratch to
reach #100. Go for it!

Richard you might profit from some technical reading there...FYI when you sit a magmount antenna on any metal surface it uses the metal as a 'counterpoise' or 'ground'. That's why they're so popular, people use them on top of their cars as a very portable and convenient antenna. Every ham should have one, they're very convenient as an emergency antenna, stick it almost anywhere. (almost, I said!).

You don't need a direct connection (DC) when dealing with RF you see, ever notice those 'through the glass' antennas?.

Thanks Roy:

Many folks do not seem to understand why things cost more in some parts of the world than in others.

The blame can almost always be placed at the feet of politicians.

The costly admistrivia which you so coherently described further up the thread comprise "non-tariff" barriers to trade.

Free trade, as perhaps best demonstrated by the efficient way the internal US domestic economy works, with very few inter-state barriers to trade, often illustrates how low prices can fall in an efficient trading system. Economic barriers, even if they are not called that, set up at political boundaries by politico's ultimately almost always do the citizens within the "protected" areas a dis-service.

Sorry, just some unsolicited commentary from a "free trader" who used to live behind tariff barriers and used to pay high prices.

It's probably TACAN, the military version of VHF Omni Range. In
the states the FAA co-locates both VOR and TACAN stations and gives
them a common ID. Also, the 1120 MHz frequency he reported jibes
perfectly with the allocation for TACAN.

And I agree with Jynx, we really didn't need to have a half
megabyte of .WAV file attached and so widely broadcast.

Hummm, myself, I would probably revert to my elevated GP. That was
always good for 2 s units to the west coast from Houston over my dipole.
Of course, you may not want to mess with on eof those. You might
consider phased dipoles. " parallel to each other" , or maybe even an
extended double zepp. The EDZ good for 2-3 db over a dipole broadside.
The phased array, maybe 4-5 db. I tried the phased dipoles once on 40m.
They worked quite well, and had a decent F/B ratio also. MK

I want to use the antenna on several bands and in both "modes" (top of loop open or closed). I can see adjusting the feedline length to resolve a problem on one band, but is this practical for 30, 20, 17, 15, 12, and 10 meters.

Hi Gord,

Yet those who describe replacing a thru-glass or mag mount with a
solid metallic connection invariably attends reports of better
performance. (It also matches my experience.)

The following is a general response to those various posters that
responded to my queries.

And still no one can respond to the discussion of currents and return,
or where this capacitance falls in the circuit. A capacitor with one
lead open does not exhibit very much capacitance except through a
third body (which also remains un discussed). At best, the sheet
metal presents an intermediate plate, and by common experience this
appears to be a poor solution ranking down there with the radiating
dummy load that "always" matches.

Anyone know the dielectric constant of this magnet? Or, more
importantly, its dissipation factor at resonance? Given that nearly
every mag mount that I have observed appears to have the common
ferrous magnetic material bound in a vinyl disk, it would do well to
remember not all ferrites are benign substances transparent to the
passage of RF.

It certainly depends on frequency. Big problem on 160m. No problem at
all on 70cm.

I have a problem with RFI with a new dipole and looking for some suggestions.

20 meter dipole well tuned, <1.5:1 SWR, new balun up 40 feet suspended by steel poles. 50 ohm decent quality feed line (RG-8X) approx 60 feet long and radio (IC-735) on a second floor office with a large solid ground wire directly to two 5 foot ground rods in a moist seattle soil.

My RF audio is getting into everything electronic between my house and the neighbors. I have a band pass filter, but this seems more like my signal is getting rectified in the audio section of my stereo receivers and my neighbors.

Any ideas on how to get this under control?

Thanks, Michael K3MH

> these tests will be published.

I look forward to seeing the published results. I assume we'll also see a comparison between the tribander and a dipole or other antenna with known gain, and the number of dB these "S-units" represent. Otherwise, the results are meaningless for any objective purpose.

> If you recall, the un-named vendor of whom you speak once offered to provide an
> antenna to anyone who would conduct tests with certifiable results. The offer
> went unheeded.

This isn't surprising. Why should someone pay for tests which the vendor should do in the first place?

> Alternatively, a "professional" test range is extremely
> expensive. I suppose you believe that everyone who starts a company with their
> own money has unlimited financial resources - which was not so in this case.
> They preferred to invest in future growth rather than squander resources,
> settling a pissing match. Your assertion of hesitancy is without basis.

Yes, a professional range is expensive. But all the vendor had to do to get a free test, with me paying the expenses, was supply an antenna which met the claims he was making. If he had, it wouldn't have cost him

a dime. The only reason I could see that he didn't take me up on the offer is that the antenna didn't meet the claimed performance. Can you think of any other reason?

You wouldn't happen to be that vendor, would you? Seems to me his name was Chuck, also.

> Perhaps the results this shoot-out, conducted by folks with uncompromised

> BTW, after 6 years, one would suppose that at least some of the users of these
> antennas would have noticed a discrepancy in the vendors claims, and this has
> not happened!

It's interesting that some objective effort is being made to verify claims only after six years of making them. But I'm glad it's finally being done. The results will be meaningless, though, unless the tribander or whatever the reference is, is carefully measured against an antenna with known gain. Otherwise, all you know is how the antenna stacks up to an antenna of unknown quality.

> By your tenacious stance against any and all possibilities that this "impossibly
> good performance" - as you say - cannot be so, are you not implying that the
> folks who use and love the performance of these antennas are either too ignorant
> to notice otherwise or are "living in an illusion" as your colleague Brian B.
> once suggested? :-)

I make a distinction between satisfaction with the product and the claims made for it. For example, a car dealer might claim that his Corvettes produce 1,000 horsepower. If the purchasers never get into a real race with a Corvette of known horsepower, they'll likely be completely satisfied. (Or if they do race, they might conclude that the other 'vette is a kHP machine too.) The situation with amateurs and antennas is much the same. Vendors feel they need to impart their antennas with magical properties, newly discovered physical laws, and impossible gain to sell them. Amateurs find the front/back ratio good, the gain modest, the SWR reasonable, and the construction good, and are satisfied. They've gotten a fair value for their money. But that doesn't make the claims true.

Very, very few amateurs are able to tell the difference between 4.5 and 6 dB gain with respect to a dipole, which is about what the discrepancy between believable and claimed performance is. Shucks, almost no amateurs even have the slightest idea of how much the S-units on their meters represent, so they can't tell 4 dB from 12. All can notice front-back ratio, though, which is quite good on most of these two element beams. And a gain of 4.5 dB is noticeably better than a dipole, which they also notice. I'm not being critical of this -- after all,

it's just a hobby. But that's how it is.

> Enough said for now. Perhaps after the shootout results are published I will
> feel compelled towards further comment!

I look forward to it. And to knowing to whom I'm talking.

I've had one for several years, it's been my only HF since I went on the air in 96 after buy the house. I've found it to be a mixed bag. It seems to work great on 10-20 meters, and 40 doesn't seem to bad either. I've yet to be able to tune an acceptable swr on 80 meters though. It's supposed to come pretune for 3900 mhz on the 80 meter band, vary narrow bandwith. It's controlled by the capacitor cap at the top. I probably need to check that whenever I get around to taking it down for a checkup. I've found it to be a good performer otherwise for anyone wanting a limited space vertical (and mine is only mounted on a tv pole strapped to the side of the garage, with the base only starting about 3 feet above the garage roof, so it isn't guyed). You might want to check out the review on eham.net.

With the SWR listed your antenna is working well. The difference between
1:1 and 1.7:1 is imperceptible to both your transmitter and the receiving
station. For some reason there is a prevailing mentality that SWR must be
1:1 for proper operation. The reality is that SWR just isn't that important
when compared to other performance parameters such as resonance and
efficiency.

Fraser,
The area of noise cancelling has been around for many years - back into the 1920s or 1930s. It started with passive LC networks for phase and amplitude adjusment and has evolved to the use of digital signal processing techniques for the most exotic systems. The techniques have several different names but use the same basic technical concepts. The current units available for amateur use are the Timewave ANC-4, the MFJ-1026 and a unit made by S.E.M. on the Isle of Man. A good summary with some QST and CQ magazine references and a homebrew design can be found at: http://207.108.137.61/n5ar/n5ar.htm

Info on the ANC-4 is found at: http://www.timewave.com

->How many magmounts do you know of that make an electrical connection
->to that same metal desk or filing cabinet (or car roof top for that
->matter)?
->
->73's
->Richard Clark, KB7QHC

All of them. The metal of the magmount is capacitively coupled through the very thin sheet of plastic intended to keep the magnet from scratching the automobile paint. I haven't measured it lately, but as I recall, you get several hundred pf of capacitance between the car body and the magnet, which at two meters is damned near a dead short to RF.

You're doing pretty well already at 3 or 4 S points. Assuming all the
noise originates from one spot (unlikely) you may do better with
a dedicated device. I have the ANC-4 and it is good within
the limitations of such things,

There have been several described in the 'Amateur Radio' mag.
published by the WIA here in Australia. The most recent was a
decription of how the writer used an old ant. tuner with a remote
wire and fed the signals into the rig with a 'T' piece.

Obviously one wouldn't build a tranmitting atu just for that
but a simple device in a little box would do the same thing.

You have almost got the same setup already! :-)

Cheers.

3486. High School Project/Packet Radio

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-02 03:40:33 UTC
From: Greg <gfischer4@mediaone.net>
Message-ID: <3A286F6C.EA9FC8F@mediaone.net>
Source record: 175352

Hello everyone...

This'll be a tough one - get ready...

I'm a high school geek from Michigan who knows absolutely nothing about am. radio, other than the fact that it exists (I went to Dayton Hamvention in 97 or 98, but that's irrelevant... :)). Our physics and engineering departments are pairing up to build 8 foot tall rockets and launch them in competitions (with FAA clearance). Part (most) of the competition involves designing a payload and doing something somewhat useful with it. I came across TINI (http://www.ibutton.com/TINI) chips and, later that week, amidst a linux (http://www.linux.org) kernel recompilation, I noticed Am. Radio support, which I had always completely disregarded. I thought about the possibility of combining the two and broadcasting temperature information (or barometric pressure or GPS data, etc...) live, while the rocket is in flight, to a computer on the ground and displaying it real-time.

The one major limitation is the amount of size in the payload section of the rocket. I BELIEVE (I'd have to check to make sure) that the rocket is six inches in diameter the payload section is about a foot long. I did a little research (emphasis on little) and determined that in order to broadcast data, I would need a Terminal Node Connector (?), which appeared to be a rather bulky piece of equipment. The other issue is licensing. It's my understanding that not just any fool can pick up an am. radio and start talking. What kind of a license would I need to broadcast data? How much would the equipment cost? I understand that this is probably going to be a substantial investment of time and money, but if we could get it to work, it would be REALLY cool.

A google search (http://www.google.com) yielded this page (http://www.arrl.org/news/stories/2000/10/10/1/?nc=1) which suggests that a Japanese packet radio group has had some success in implementing packet radio on TINI chips, so that issue may be solved.

This may also be overcomplicating a simple task. If anyone knows of a better way to get that data to the ground, I'd be grateful for all suggestions (PPP via cell phone?).

Thanks for taking the time to read this, any assistance is greatly appreciated.

-Greg

I also have a 989(C) and have noticed tuning problems, particularly when
trying to extend the range on my Butternut HF6VX vertical. I suppose
that there is a limit to the impedances that can be matched effectively
with in this situation. For example, the normal 2:1 SWR tuning range of
my Butternut is around 50 khz, and I can spread it out to around 100 khz
with the tuner, but no further. I wanted to be able to cover the SSB DX
window (3790-3800 and the "net" end of the band ~3950) at the same time,
but it was never possible.

Curt, try various lengths of feedline with the HF6V. I would bet that
you can find one length that will allow you to tune the DX window and
another that will allow you to tune around 3950.

Remember that when not terminated in Zo, a transmission line becomes an
impedance transformer that is doing part of the overall job of matching
your 50-ohm transmitter to the actual antenna impedance. Adjusting the
length of the line is one of the easiest ways to control that impedance
transformation and make it work for you instead of against you.

My experience with my 989C and 4 different antenna systems here has been
very positive. I can tune any of the antennas over entire bands with no
problem. The antennas are

88 ft EDZ for 20 meters - ladderline fed

full-wave horizontal low 40-meter loop - ladderline fed

Butternut HF9V ground-mounted over 60 radials - coax fed

4 half-wave dipoles in parallel on 80, 40, 30 and 20 in the attic - coax
fed

All of these antennas either cover and can be made to cover all bands
80-10 with no problem using the 989C. Maximum power here is 100 watts
and most operation is at 5 watts on CW or 30-50 watts PSK31.

The ladderline-fed antennas are connected through 12 ft lengths of
RG-213 and W2DU current baluns from the 989C to the ladderline.

performance
> broadside than you think.

Mark, you are probably right about that. Doc suggested that as well. It may be a waste of time and effort to run another dipole at a right angle to the East-West wire. My current 40M antenna is up about 45 feet in the center and about 30 feet at the ends. Modeling it shows what you have suggested, it also radiates most of the energy at a very high angle.

I am trying to put a better signal to the West coast from Iowa. So far a full sloper (1/2wl) is showing a little improvement over the inv-vee in that direction, but I keep thinking there has to be a better answer.

Dear Roy,

I don't like Spam and I am only trying to avoid it. My posting anonymously - or, semi in this case - is not intended to be a covert act! You have always posted in a courteous and professional manner and I respectfully propose that your disparaging innuendo regarding my intent fell below that standard.

There is a shoot-out being conducted by RAC (Radio Amateur Canada) using a popular tribander and a tribander with critically coupled elements from the antenna vendor of whom you speak. Each tribander is on a separate 55' tower - I don't recall the exact separation between towers. The popular tribander has a 20ft boom the critically coupled tribander has a 12 ft boom. The popular tribander is being outperformed in every case, and on all bands, by a minimum of 2 to 3 S-units by the critically coupled tribander that you say has "unsupported claims of impossibly good performance". Up to this point, the evidence in support of critical coupling robustness is quite compelling, and the results of these tests will be published.

If you recall, the un-named vendor of whom you speak once offered to provide an antenna to anyone who would conduct tests with certifiable results. The offer went unheeded. Alternatively, a "professional" test range is extremely expensive. I suppose you believe that everyone who starts a company with their own money has unlimited financial resources - which was not so in this case. They preferred to invest in future growth rather than squander resources, settling a pissing match. Your assertion of hesitancy is without basis.

Perhaps the results this shoot-out, conducted by folks with uncompromised credibility and no self-interest in the results one way or the other, will finally put this issue to rest. Although test range performance analysis is always valuable, it is my position that *real world* performance is equally as valuable... perhaps even more so... after all, how many Hams operate on test ranges?

BTW, after 6 years, one would suppose that at least some of the users of these antennas would have noticed a discrepancy in the vendors claims, and this has not happened!

By your tenacious stance against any and all possibilities that this "impossibly good performance" - as you say - cannot be so, are you not implying that the folks who use and love the performance of these antennas are either too ignorant to notice otherwise or are "living in an illusion" as your colleague Brian B. once suggested? :-)

Enough said for now. Perhaps after the shootout results are published I will feel compelled towards further comment!

Best 73,

Chuck

Maybe, but in my case, thats the way it worked out. I had one car where I had a larson mag mount 5/8 2m antenna on the roof with the larson magnet mount. "square looking deal" It worked fairly well, but after a period of time, I had to scrap the mag mount as I had knocked it off the roof one too many times and it was trashed. So I installed the same antenna onto the same exact spot except with a hole mount. I noticed quite an improvement in antenna performance with the hole mount. More than I expected. So in my case anyway it did make a difference. MK

The real reason mag-mount antennas have that vinyl base is to prevent the
mount from scratching your car's finish as the antenna - and car - vibrate
while you drive.
(I've seen what a mag-mount 19" homebuilt two-meter antenna does as it
"chatters" along.)

3499. RG-58 co-ax cable v. RG213?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-03 00:00:00 UTC
From: Colin Marks <cbm@zip.com.au>
Message-ID: <3a2a42a6.b6a16@nancy.pacific.net.au>
Source record: 175304

I need to install new feedline about 70 feet long for my 20m antenna. No other band will be in use. . Leaving myself a large margin for error , I would like to feel it could safely handle 800 watts CW or about 700 SSB. (I normally run much less - legal limit here for SSB is 400 watts PEP). I am not worried about possible power loss. My concern is the power limitations of RG58 without causing damage or deterioration to the cable.
I have previously used RG58 for part of my feedline for many years under similar operating conditions with no problems but this installation will be the whole feedline.
I prefer to avoid RG213 or similar heavy-duty co-ax because of high-cost and rigid stiffness to work with.
Any comments?

Colin VK2LV Sydney

Hi Sydney-

I looked this up last week, and--as I recall--300 Watts is the recommended power limit at 30 MHz for RG-58 and 350 Watts for RG-8M (mini-8). Although I've pushed a kW through RG58 into low-SWR loads at 30 MHz during tests, I don't recommend it as a general practice. Here's why: A friend of mine was running 1500 Watts through RG-8M with no problem until one leg of his dipole fell down in a wind. To his dismay, the elevated SWR increased the RF voltage past breakdown, frying the dielectric in the cable and taking several components in his amplifier along with it.

The flip side of the coin is weight. RG-58 and RG-8M causes a lot less sag than RG-8 or RG-219 for suspended antennas. So much so that I run 1000 Watts PEP into my 75 and 20 meter dipoles through RG-8M despite the increased risk. However, because of my friend's experience, I look out the window before I turn on the amp to make sure everything's still up. I also periodically check SWR with a handheld analyzer to confirm that nothing is full of water or deteriorating out there.

What I do is use heavy duty '450-ohm' ladder-line and make the feedline
either 62ft long (one wavelength) or 93ft long (1.5WL).

i would not trust rg-58 with that much power. try rg-8x if you need a good
mid-range cable for higher power and flexibility.

>

Hi Gord,

My mobile installations (we are talking about mag mounts typically in a mobile situation, are we not? Aside from the original question that is.) usually have at least 6 to 10 feet of coax running in very close proximity to the sheet metal of the chassis (certainly for the extent under the carpet for my rigs). Using RG-58, this presents a surface area of some 30 odd square inches located roughly .05 inch from the other plate presented by the sheet metal. By my rough calculations this presents about the same 300 pf as your offer of the mag mount.

If the mag mount's 300 pf is a dead short, then this must be in parallel with an already established dead short from the coax feeding it. The mag mount thus appears to be redundant and not a very notable distinction. Reductio ad absurdum would lead us to believe that aside from the grip of the magnet, there is no other benefit and if we could conspire to hold an antenna without it, it would be completely unnecessary. However, this is not my logic and experience indicates otherwise.

Again, to the general board: The logic of the arguments presented so far still far short of actually explaining the mechanics (much less the circuitry) and why the lack of benefit when compared to a direct connection. I still see discussion arranged around capacitors with dissipation factor unknown and dismissed simply for that reason.

Colin and Doc,

Thanks, I tried it and the RFI is certainly a bit better now, but still there. Would you ground then to the outlet ground then? With these new (<15yr) hourses, the grounds arent the most solid with all the plastic piping used these days.

Any suggestions on further reducing RFI? Does the quality of the shielding of the coax make much difference? I also have a 1/2 KW amp which kick up the RFI as well.

Again, thanks for your help.

Michael...several years ago, my shack was in a room over the unattached garage outside my home up about 10'. Getting a good RF ground was a real challenge. I bought some 12" copper flashing (used on roofs) from the local lumber yard and ran it from the station down to three copper rods below. All of my RF feedback and hot microphone problems went away. Just remember to scrape away the protective coating used on the flashing before connecting it to your grounds.

Another thing I did in a similar situation a few years later was to take an old piece of rotor cable and cut three of the wires to a 1/4~ on 10-15-20mtrs (I didn't operate lower than those) and attach it to the ground lug on the rig. That also got rid of my hot microphone and rf feedback.

And last, are those metal poles you're using, well grounded too?

Hi Jim,

The portion of the message you did not quote consists of:
> I still see discussion arranged around capacitors with
>dissipation factor unknown and dismissed simply for that reason.
As Air is NOT the di-electric in this capacitor, there must be some value other than 1.00. It also follows that there is a corresponding dissipation factor which still remains unstated - in rhyme or free verse.

In other unquoted material:
>Anyone know the dielectric constant of this magnet? Or, more
>importantly, its dissipation factor at resonance? Given that nearly
>every mag mount that I have observed appears to have the common
>ferrous magnetic material bound in a vinyl disk, it would do well to
>remember not all ferrites are benign substances transparent to the
>passage of RF.
I posited that this medium consisted of a magnetic material in a vinyl binder, others have posted that there was simply a vinyl protector. On a casual inspection of one of my own I found a foam plastic.

If that magnet is not one in a vinyl binder, but is rather the more ordinary ceramic permanent magnet, then the material of that ceramic, the ferrite could easily be VERY lossy if found between the plates of a capacitor.

Given there is a disconnect between the claims of adequacy on the part of mag mounts and the counter claims of improved performance by simple ohmic connection to the same sheet metal, it becomes apparent that the short fall of performance must be found in the difference of the two

methods of "coupling" to the sheet metal.

The argument of "capacitance" is not an answer for the difference, unless some loss is involved. The simplest source of loss in this regard would be dissipation of the dielectric. Whatever media that is used is suspect barring other discussion.

Source record: 175317

I think I'd crank reliability into the equation. I've used RG-58 for many years with up to 300 watts CW and PEP SSB with no problem. I don't think you'd have any problem at this power level if you keep the line SWR low (which should be possible with the single band dipole). I don't know about running it at twice this power for extended periods though. What I'd think about is how much of a pain a line failure would be. If it's a minor job to replace it, and you're not worried about failure during a critical contest or emergency, then I'd probably go ahead and push it. Otherwise, I'd opt for heavier cable. RG-8X might be a good compromise, since it should take a bit more power than RG-58 (if you don't bend it much) and still be reasonably light.

I am hoping that someone out there can answer this question for me. I am currently running a VHF/UHF mobile antenna mounted on my balcony and am getting approx. 35-50 mile range. I would like to extend that range. I unfortunately do not have access to the roof to mount an antenna. I have heard people recommending the crushcraft AR270 for its height and quality. Will this give me a large improvement over my mobile antenna ? My mobile is just fastened to the balcony using a lip mount. Also another recommendation I have heard of is to add a pre-amp to improve the reception of those far off signals. Any other recommendations or proven solutions are welcomed and thank-you ahead of time.

Hi Colin,

For performance of RG-58, under various ventillation conditions, at any RF power up to melting point of polyethylene, at any frequency up to 1 GHz, at any SWR, download (in a few seconds) program COAXRATE.

And the same for any other solid polyethylene coax cable.

You will find coax cables longer than 1/4-wavelength fail at HF due to overheating before they fail due to voltage breakdown.

It is entirely up to you to decide at what power the temperature rise is excessive. Nicely warm or when it becomes too hot to handle ?

One possibility would be to use RG-400 (like RG-142, except with a stranded center conductor). It is about the same diameter as RG-58, has a teflon center conductor and is double-shielded). It's not necessarily a low-cost solution, however. I used it once for a 80 meter dipole to keep the weight down compared to RG-213 and it easily handles a KW or more.

I'd try Doc's idea first. Unhook the ground and see if that will help.
When using a dipole, a ground to the rig is not really needed anyway. If
you still have the RFI, you likely are whacking out your neighbors with
fundimental overload. If this is the case, and your antenna is as far
from them as you can get it, they will likely need some filtering to cut
the interference. A filter on your end will not effect fundimental
overload, only any spurious output. MK

I did a shakedown today in preparation for the 10M Contest next weekend. Did a couple of hours of 250+ Q's per hour rates. Wicked QRN (from Aurora??) but signals were strong and noise blanker worked well.

The 10M Fractal Quad yagi did well with its new coax; SWR is better than 2:1 from 28.0 to 29.4. Technical details can be seen on the ham page of:

http://www.fractenna.com

NOTE the ham page will be removed in the next week and then migrated over to another link. I will provide an update when the transfer occurs.

Here is a 5 minute slice of the nice EU Q run, on 28505.0 KHz, with a JST 245 at 130 watts, from 1430-1435 UTC:

3518. HP803A VHF Impedance Bridge

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-03 00:00:00 UTC
From: atkes@imap1.asu.edu
Message-ID: <90ek9d$9io$1@news.asu.edu>
Source record: 175373

This weekend I bought an HP-803A VHF impedance bridge at a local hamfest. It did not come with a manual, but looking inside, there doesn't seem to be much to it. The generator input is connected to what appears to be a dual differential adjustable waveguide attenuator each end of which then couples to one of the two ends of a transmission line loop with an adjustable tap which goes to the detector. I surmise that the way it works is that the generator drives a 50 ohm standard hidden inside the waveguide attenuator as well as the unknown. Each signal is separately attenuated and fed to one end of the transmission line. The differential attenuator adjustment is calibrated to give the impedance magnitude and the transmission line adjustment gives the phase.

My problem is that a good 50 ohm load connected to the unknown connector balances with a reading of 38 Ohms. Hooking various lengths of 50 ohm air line to the unknown connector, the bridge balances within a degree or 2 of a phase of plus or minus 90 degrees and if I remove and add a shorting cap across the airline the product of the open and shorted impedances are 38 plus minus 1 or 2 ohms squared. I have tested this from 60 to 500 MHz and the results are the same throughout that range. From the above results I can determine the effective length of the front panel transmission line, and the results are consistent with the bridge giving the true impedance multiplied by 38/50. From this I am assuming that the internal 50 ohm standard has changed value to 38 ohms presumably because someone damaged it by feeding it too much power.

My questions:
1. Am I correct in my guess as to how the HP803A works?
2. Am I likely correct in my guess as to what is wrong?
3. Does anyone know if this is repairable with available parts? That is, will something like a 50 ohm chip resistor fit in there. The coax from the generator cable has a solid outer conductor, and getting at the resistor which I assume is inside the wave guide attenuator would require undoing a fair amount of plumbing, so I would prefer not to take it apart until I know whether or not it can be fixed.

I can of course just multiply the impedance measurements by 50/38 and forget about it, but it would be nice to have it working as it was intended.

Thanks and 73, Kevin w9cf@ptolemy.la.asu.edu

3519. Pi Tank matching network for any PA

Source record: 175374

Dear NewsGroup Readers,

Now available for the use and entertainment of armchair PA linear designers. To professionals and amateurs alike, all at the same ridiculous low price.

******** Program PI_TANK.exe ********

Input data : Frequency, RF power output, peak RF plate volts, external load resistance, phase shift through network, Q of coil.

Output data : Values of C1, C2 and L, reactances of C1 and C2, resistance of plate load, efficiency, watts lost in coil, network Q, Bandwidths at the 1dB and 3dB points, network rejection in dB of 2nd, 3rd and 4th harmonics.

Usual facilities available for sweeping input data over wide ranges in fine increments.

Will unbelievers please note that the internal resistance of the PA device is not needed.

Program PI_TANK proves that the ARRL Handbook table of C1, C2, L values for PA pi-match networks are accurate to within +/- 10% or better.

Fully tested before issue. No beta testing in this house.

Only 44 Kilobytes. Download PI_TANK in a few seconds from website below. Run immediately.

Source record: 175377

American cable manufacturers appear to rate the power handling capability of coax in watts as that power which causes the temperature to rise to 85 degrees Celsius which is the softening temperature of polyethylene. It becomes runny at 120C. Actually, long term exposure of the pvc sheath to that temperature causes irreversible hardening and loss of flexibility.

On that basis the wattage capability of a length of coax depends on whether it is used in Florida on 4th July or outdoors in Alaska on Xmas Day. Its all very airy-fairy.

85C will raise blisters in a few seconds on your hands. Most people would derate their coax to a far lower temperature, not because they are scared of being blistered but because it is painful just to think of all that beautiful and expensively generated RF power running to waste.

It should not be forgotten that cable attenuation increases with frequency. This means that at 144 MHz a cable will handle only about 1/10th as much power as it will at 1.8MHz.

Using the ground at the convenience outlet is not a good
idea. When you do this you in affect make the house wiring
part of your antenna system. The last thing you want is
your antenna closer to the devices being interffered with.
Shielding of the feed line makes little difference in this
case.
What you might do is to use a counterpoise for a ground.
run it along the base-boards, across the floor, etc. If it
helps, then you can try hidding it. You want to make the
counterpoise out of insulated wire. It developes a high
voltage at the end, so be sure to insulate the end of the
counterpoise.
The amplifier is going to make everything worse, but if
done correctly, the counterpoise should handle it too.
Good luck...
'Doc

Just wondering if anyone out there has purchased the antennas offered
by this company out of Western New York....?

Comments, input, advice?

I'm looking for future reference regarding purchase of this type.

Thanks for anyone that knows something about them.

>All of my RF feedback and hot microphone problems went away.

I'm glad you fixed your problem, but you still don't have an RF
"ground". You have a piece of copper flashing 10 feet long running TO
an RF ground. If you measure across the ten foot piece while
transmitting, you will find a voltage drop across it, and where you
have a voltage drop, you do NOT have a ground.

Just be glad it works. :-)

If you wish to read how the GAP antenna is thought to work, look at US
patent 5592183. Not a simple structure.

Of even more potential interest to this group might be their last
patent (5796369). It appears to show a structure that has been
extensively discussed.

I've built a 1/2" copper pipe version of the antenna mentioned here:
http://www.cebik.com/moxbld.html
with excellent results on my balcony. The gaps on mine are made from
CPVC pipe and fitting which fit the CU exactly. I've also made a brass
tube and Cu corners version for 70cm which uses wood dowels to define
the element spacing. There was also a QST article, earlier this year
on this neat antenna, the Moxon beam.

Not necessarily. The apostrophe is often used to indicate a plural of a non-standard word such as an acronym, i.e. QSL's or even "73's". This may be "right" or "wrong" depending on your biases, but it's pretty common.

And if I send you Best Regards and do it more than once (say to your whole family), isn't that "73's"?

IOW, get off your high horse. Go count the dimpled chad in Florida.

Source record: 175293

I have a VERY well tuned 2m j-pole antenna on my roof and now want to expand to 70cm. I don't have room for another mast so the only option I really have is to make a 'cactus j-pole', BUT, I don't want to cut any off my 2m as all the building instructions have said.
The question I have - would it work if I just removed the end cap off the long element and sweat a threaded adapter and then screw in a PVC coupler (to insulate between the two antennas) then screw in a copper adapter in the top end then fasten my 70cm j-pole to it with the stub turned 180 degrees from the 2m stub?

From: earlve3ab@igs.net
Message-ID: <3a29b80f.222640239@news.igs.net>
Source record: 175292

I have a Radio Shack Log Periodic Antenna for VHF and UHF TV..It is
the small one for a trailer ect..I wonder if anyone has tried using TV
antennas..Particularly a Log-Periodic type for 6 and 2 or even higher.
One problem right off the bat is the 300 ohm feed requirement. I would
need a broadband low loss balun and Im not sure ive ever seen such
a balun design for ham radio. The TV Balun would probably not work
on transmit over 1 watt..and might be lossy. Any help on this aspect?
The antenna is all ready to go and maybe someone would email me and
let me know if Id be wasting my time to hook some coax to it!!...73

I totally agree with the following statement by Mike from post #20 ."If I had only one antenna that I could use and wanted multi band performance from a Vertical I would choose one of the Butternut models. They have extensively tested and written their results for all to read.. (no magic Just plain proof). " I totally agree with this.
I can honestly say that I have own and operated a Butternut HF6V on 10 through 75 meters for the six years. My Butternut vertical has been roof mounted with only 4 radials and I have no trouble tuning through the internal radio tuner or with a MFJ949D versa tuner. I am only putting out 100 watts but this Butternut vertical. It works absolutley great on all bands 10-75 meters. Dan KE6TDT

That could be Richard, I have used magmounts for many years but never have tried comparing them with a direct connection.

>The following is a general response to those various posters that
>responded to my queries.
>
>And still no one can respond to the discussion of currents and return,
>or where this capacitance falls in the circuit.

OK...the capacitance merely connects the braid of the feedline to the counterpoise, quite simple actually, I'd think that there'd be little difference between a magmount sitting on top of a car and a vertical antenna with four radials each fed with a capacitor of say 200 pf.

Hey, there'd be very little difference (at VHF) between a direct mechanical connection and a 300pf or so capacitor. ~300 pf is for sure a dead short at VHF.

> A capacitor with one
>lead open does not exhibit very much capacitance except through a
>third body (which also remains un discussed).

Open?...it's not open Richard, the braid is connected THROUGH the capacitance to the counterpoise. Very little difference than connecting it directly. imo.

> At best, the sheet
>metal presents an intermediate plate, and by common experience this
>appears to be a poor solution ranking down there with the radiating

Regarding that QST article describing the large kite used to suspend a vertical radiator, the Dupont Tyvek material used for the kite isn't sold (or needed, for that matter) in Southern California! I found it in a Home Depot on a business trip to Portland, but it was only sold in very large 100-foot rolls that were way expensive.

What are folks in warm climates to do? What do the rest of you do when you only need ten feet of the stuff?

I drive up to Boulder and buy it by the yard from Into The Wind.
They have a Web site and take mail orders.
http://www.IntotheWind.com/ Look under "Supplies".

The Tyvek that they sell is not the same as the housewrap. It is
lighter and is 60" wide. I haven't built a kite using it,-- I use it
backpacking as a ground cloth under my tarp.

Been an avid kiter over the years and having built kites up into the
150+ sq ft. range I've always used my local kite shop for materials.
The "Into the wind" catalog also has supplies aplenty if you lack a
local source.

If the government lowered the fee to $1.00, the broadcasters would quickly up the ante to whatever the spectrum was worth, which would certainly be >$20,000.00.

> Licensed by the government, made possible by the government's extreme
financial
> manuvering and (most probably) heavily controlled by the government as
> a monopoly made possible by the government.

It is not being "made possible by the government." It is being made possible by the fact that only those who are in the broadcast business are willing to pay the money it takes to win the spectrum auction. It would be nice to buy a new car for $1.00, too, but "they" run the price up to the point where it takes real money to buy one (and to build it, too).

> This may not bother you but, there are some who feel it is NOT in the
> best interests of US citizens as our news media (and even our
> entertainment media) should NOT be "government controlled" any more
> than it should be controlled by some outside political faction.

This is not governement control, it is capitalism at work.

> And, by making it economically unviable for the average citizen to
consider
> the debt load of a broadcast property, the government IS making sure that
> we only see news, information and entertainment as presented by the
"chosen few"
> and, contrary to what you may believe, there IS an after effect on our
> population and, most importantly, on our children who've never known a
> true "free media".

What makes in economically unviable wrt broadcast licenses is that those that are in the broadcast business are willing to pay the money. If the minimum bid were $1.00, they would bid it up to the same level that it is now.

And, IMHO, the concept that we see only news, information and entertainment presented by the "chosen few" is preposterous. There are hundreds of newspapers in this country, perhaps more if you count all the newsletters and local rags. There are hundreds of local broadcast stations, both TV and radio. The internet has given even the more outlandish amongst us the opportunity to stand on our soapbox before millions of people. We have never been more free, or had more outlets of expression and information.

This is really off topic for rec.radio.amateur.antenna; perhaps we should take it to one of the broadcasting newsgroups. Please forgive my off-topic post; the Devil made me do it. :-)

I live in an antenna restricted area. I am thinking of putting up my 8' whip
to use on the hf bands. It seems that the group prefers ladder line and/or twin
lead for most feeds. Can I use this for a vertical? How would I feed it?
Would it be better to use rg58?

Please respond to redberdberd95@aol.com.

I used the old brown paper grocery bags cut to form sheets. Use Elmer's glue and at least an inch overlap on the joints

I used 1/2 inch thinwall conduit for the frame and bindertwine for the string around the frame. The thing was about 7 or 8 feet tall.

Careful and launch only in light winds and don't get caught in the string <:-)) A kite this size is usually more than one person can hold in anything over a light breeze.

Most any larger hardware store sells it and other window covering material
that will work, but I still like the old large, brown paper grocery bags.

It's been discussed a whole lot here. Do a Deja-News search for the antenna and you'll find plenty of long discussions on the antenna here. It was also reviewed by QST back in the early 80s, and if you join the ARRL, you can access that review at the ARRL members-only web site. Bottom line, the B&W more or less equals a dipole above 14 megacycles. Doesn't do too well at on the lower bands.

I would also recommend the Gordon West books to anyone.

The ARRL book for the Advanced test I used in 1993 was a horror. It was presumptuous and condescending; useful only because the test questions were included. My feeling at the time was that the ARRL did not want anyone to pass the test.

I am unaware of a Gordon West League. How is it that our national amateur radio organization can not provide more helpful study material then a single individual?

In 1993 I wrote the ARRL asking that very question. I presume they are still drafting a reply.

The physics experiment he described demonstrates that wavelength is a function of the medium it traverses (the propagation velocity is different for each of the two ropes), and also that a reflection occurs at the boundary and again at the termination - in this case, a short circuit analogy. A sliding ring termination could be used instead of a doorknob to demonstrate the open circuit analogy.

Curtis,
We (Elk Antennas) make a small (24 inch boom length, 5 elements) 2M log periodic antenna that should improve your situation. It also works well on the 440 band, but we also make a 440 log (21 1/2 inch boom length, 7 elements) that many people use in apartments and homes where they are not allowed to put up outside antennas.
If interested, e-mail me and I'll send performance data and photos.

Happy holidays and best wishes from ray, w6fya for Elk Antennas

As long as you have a good match to the antenna rg-58 will handle 400
watts no problem. If you were under 2:1 "IE dipole etc" you could
probably run twice that much on 20m. 213 will have a bit less loss. Not
drastic on 20m though. MK

>I always thought that it was your call letters that got you "that job", heh,
>heh.

Actually, it was the other way around. I was KA1CV when I was hired by ARRL HQ. After a few years, I started my RFI thing, and, when the vanity program came along, at first I poo-pooed the idea. Then one day, I jokingly said that the only call I would consider getting would be W1RFI. Then I realized I really WOULD consider it. Still, I vacillated. Then, I asked myself, which I would regret more when I retired, giving up KA1CV, or not getting W1RFI when I had the chance. The Extra window was open, so I sent in the app, with one callsign on the list. I got it. :-)

This is a common myth. The apostrophe indicates more than possessive case.
From Webster's: "apostrophe - a mark ' used to indicate the omission of
letters or figures, the possessive case, OR THE PLURAL OF LETTERS OR
FIGURES." (emphasis mine) "Figures" in this case means numbers.

So if someone wants to pluralize 73, it would be 73's.

My father is an avid ham radio operator. He recently passed an advanced license exam and I would like to get him either new QSL cards or a gift certificate for him to design his own for Christmas.

Can anyone recommend a good QSL card dealer? US only please.

Thanks!

Lee

Hi All,

One thing you have to remember is with fixed antennas you need to be able to rotate phase in the phase shifting unit at least 360 degrees to get a null in every possible case. At the same, amplitude (gain or loss) should be stable and fully adjustable.

Most units do a poor job of this, including the Timewave. The MFJ unit is by far superior to all other units on the market. It has less than a few dB ripple as phase is adjusted, and allows phase to be rotated almost 360 degrees.

To save you a little homebrewing time, I looked at this site:

>of Man. A good summary with some QST and CQ magazine references and a
>homebrew design can be found at: http://207.108.137.61/n5ar/n5ar.htm

The noise canceller in figure 2 won't hardly shift phase. The phase control will change amplitude from zero to maximum, and at the zero crossing point phase will flip abbruptly 180 degrees. It looks like the DeMaw phasing unit, which has a similar action.

The slight phase shift you can get is due to changing load impedance on the small capacitors by the transformer. That shift is a few degrees at best, and so what you have is basically an abbrupt phase-flip.

The unit in figure 3 can only shift phase 0-90 degrees.

The unit in figure 4 is a mess. On some frequencies, it should shift phase pretty well...but it will be amplitude and frequency sensitive.

I use several phasing units here, not to cancel noise but to steer nulls and lobes on large receiving arrays. My design is similar to the MFJ unit's design. I can rotate phase 360 degrees with less than 1dB of amplitude shift with that system, so I can null any unwanted signal from any direction.

Most of the stuff in articles just doesn't work well, or at all.

If the allocations are not worth what those minimum bids are, no one will bid. If they are worth it, even if the minimum bid was $1.00, the bidding would very soon be up to that level, so the net effect would be the same.

I don't see any consipiracy here.

Ian, you misquote me.

I checked the accuracy of a *Table* of L & C values - not a formula.

The Pi-match L & C table is in the 1992 edition of the ARRL Handbook and was donated by a ham. Some of the entries in the table are 10% in error but are quite accurate enough for their intended purpose. I was not complaining - just a reminder that radio amateur publications are not infallible bibles to be religiously quoted from.

If your Excel spread sheet (I was unaware of its existence) ignores the intrinsic Q of the inductors then it must be less accurate than program Pi_Tank which takes it fully into account when calculating the network Q.

It's not really a conspiracy, per se. It's just that, with an
$1,850.00 (mandatory) application fee and a $20,000.00 (as an example)
UP-FRONT "minimum oening bid" to even be considered as a contender in
the auction, PLUS the cash required for construction... I believe you
can see, based on this, exactly why Mr. and Mrs. Average Citizen
America have abdicated the throne of broadcast ownership and nearly
every "possibly profitable" (as in "making the payments and financially
solvent") property in the country is being bought up by what will soon
be the "United States Broadcasting Company". Licensed by the
government, made possible by the government's extreme financial
manuvering and (most probably) heavily controlled by the government as
a monopoly made possible by the government.
This may not bother you but, there are some who feel it is NOT in the
best interests of US citizens as our news media (and even our
entertainment media) should NOT be "government controlled" any more
than it should be controlled by some outside political faction.
Some of us prefer "truth" to "propaganda" (which our government is
just as prone to dish out as any other). And, by making it economically
unviable for the average citizen to consider the debt load of a
broadcast property, the government IS making sure that we only see
news, information and entertainment as presented by the "chosen few"
and, contrary to what you may believe, there IS an after effect on our
population and, most importantly, on our children who've never known a
true "free media". (As an example, look at the results of the Florida
newsmedia "jumping the gun" while covering this years presidential
election... It DOES make a difference!)

For an alternative approach, anyone with access to Excel can download a
spreadsheet from my website which implements the ARRL formulae for
designing both Pi- and Pi-L networks.

It doesn't have some of the bells and whistles of Reg's program, but has a few extras of its own, including:

* Both Pi- and Pi-L networks calculated from the same input data
* A number of different ways to estimate the anode load impedance
* Allowances for stray inductances and capacitances
* Allowance for parasitic suppressors
* Calculation of VHF parasitic frequency (if you click "Enable macros" when the spreadsheet loads)

Being a spreadsheet, the "What if?" feature is built-in, and the formulae and internal workings are there for all to see.

What really prompted me to mention this is Reg's statement about agreement with the Handbook formulae within 10% or better.
The network design formulae in all recent ARRL handbooks (since 1995) give *exactly* accurate impedance transformations - as determined by reverse analysis - if you ignore the unloaded Q of the coil.

Earlier Handbooks contained formulae which became progressively more inaccurate with decreasing loaded Q. They were tolerable for output tanks, but useless for cathode input circuits with a design loaded Q of 2-3.

For the record, which Handbook formulae did you compare against, Reg?
Do you get exact agreement if the coil Q is infinite?

(I'll download the program tomorrow.. right now my eyes are crossing.)

Quite possible - in which case nothing you do at the transmitter will make much
difference.

The ground wire ideas suggested by Colin and Doc are good ones. But the
affected devices probably need help, too. One thing to do is to "toroid" all of
the speaker wires and audio cables, and try changing their length if practical.
Power cables should get this treatment too - the house wiring may be hot with
RF. Sometimes the cables are exactly the right length to be resonant in the ham
bands.

Sometimes replacing the audio cables with homemade ones of real coax helps,
because the manufactured ones are often not well shielded for RF.

Hope all is well! You are definitely missed here in Delco.

Source record: 175389

COAX TYPE RG-58

At 10 MHz : -

1.23 dB per 100 feet (per 30 metres).

300 watts continuous through power.

SWR = 1.5

Ambient temperature = 20C

In still air.

Sheath temperature rises to 45C which is quite hot.

At 30 MHz sheath temperature will rise to about 65C at which higher temperature long term effects might cause sheath to harden and crack, let in water, although polyethlylene would remain undamaged.

On a still, hot, midsummer heatwave, in direct sunlight, the sheath temeperature could rise another 20 or 25C. The inner conductor would be even hotter. The polyethylene would soften and immediate failure could ensue.

But shift your QTH to the Antarctic and with 300 watts at 30 MHz with an SWR of 1.5 to 1 you would be OK.

Alternatively, confine your transmissions to the 160 metre band, keep off FM, and you could go up to 500 watts for short periods.

Its an interesting thought that at 50 Hz and 230 volts, RG-58 would carry 3 Kwatts without any appreciable rise in temperature.

Do you have a choke in the feedline?
make a coil of the feedline as close to the feedpoint as possible. 5 or 6 turns about 6inches in diam.
This may help. Also make a resonant line to attach to the antenna connection, This will help to compansate for inadequate rf ground (rf ground is not the same as ground ground)
ARRL has several good books on the subject. Try the Radio bookstore they have a website
John

Of course, but if you plan to operate at 160M using a magmount then you got one helluva lot more problems than worrying about coupling to the counterpoise!!...like maybe getting clearance from the FAA/IC for the Airways Clearances you'll need!. :)

>this presents about the same 300 pf as your offer of the mag mount.
>

As I see it, after the coax enters the vehicle then it's no longer coupling to the counterpoise, therefore there's only a couple of feet that's lying on the counterpoise and is capable of doing any coupling at all. I'd judge that if you didn't have the RF coupling as close as you do (by the magnet) then you'd have some swr introduced because you don't have the coupling close enough to the base of your radiator, also the coupling will be unstable because of wind movement of the coax on the car roof.

>If the mag mount's 300 pf is a dead short, then this must be in
>parallel with an already established dead short from the coax feeding
>it.

But imo the couple of feet of RG-58 lying loosely on the roof is, although in parallel with the magnet's capacitance, much much less that it's capacitance so for all practical purposes won't matter.

>The mag mount thus appears to be redundant and not a very notable

>

Mine doesn't...

>Again, to the general board: The logic of the arguments presented so
>far still far short of actually explaining the mechanics (much less
>the circuitry) and why the lack of benefit when compared to a direct
>connection.

Cripes, there's almost no mechanics involved here at all...gee... The magnet merely holds the bloody antenna on the roof and acts as a capacitive coupling to the counterpoise. How could it be simpler?. The 'benefit' is (clearly) no requirement for drilling holes in your new shiny car, as well as avoidance of pissing the little woman off.

>I still see discussion arranged around capacitors with
>dissipation factor unknown and dismissed simply for that reason.
>

Say what?...

Who cares what the 'dissipation factors' are?...this is an overkill DEAD SHORT so who cares what the dissipation is?...I seriously doubt that you'll heat up that great hunk of iron stuck onto your metal roof.

>73's
>Richard Clark, KB7QHC

Richard, 73 means 'best regards', when you say '73s' you're saying 'best regardses'...if you use the apostrophe you're indicating that something (which you haven't named) belongs to the '73'. If you don't believe me then check with an English teacher. Experienced hams don't use _73s_ much less _73's_ :)

Source record: 175394

There's a chance you may still have some RF on your coax shield.

(A balun should have reduced this, so you might have a problem there, maybe withthrouting of your coax. You might check to make sure the shield and cetner conductor are still conected adn tehre's no stress on t4eh coax, and that both halves of eh dipole are connected.).

If you STILL have RF in teh house, try coiling up about 8 feet of your coax in a coil about a foot across, taped so the turns don't come apart. This should act as a choke for any remaining RF that your balun is not decoupling from the coax shield.

: the neighbors. I have a band pass filter, but this seems more like my
: signal is getting rectified in the audio section of my stereo receivers
: and my neighbors.

I suspect that your problem is that long "rf ground" run from the second
floor. It will be anything BUT an rf ground on 40 meters. Try using an
rf counterpoise instead of the physical earth ground.

: Any ideas on how to get this under control?

Moving the rig to the ground floor would help. Using wide copper flashing
for that ground "wire" would help some - it would greatly reduce the
impedance.

I doubt if you will get much more range - even if you put the antenna on
a 100 foot tower. You are pushing line-of-sight (including defraction
effects) already.

Height is everything on vhf. Mount any decent gain antenna atop a ten foot
Radio Slack TV mast, tilt the whole structure away from the building enough to
clear the balcony above yours and clamp it in place. Bend the TV mast if
necessary. More distance away from the balcony above if it has a metal fence is
better.

We are currently evaluating a CR109ARD model at 46 MHz. The manufacturer says they are vertically polarized, omni-directional, and provide much better efficiency than a rubber duck. We will be doing range tests on this model at the end of the week, and preliminary field strength probing indicates a large null (approx. 40 degrees), but this may be site/installation specific.

I can tell you one thing though, it seems to stay tuned at various ambient surrounding air temperatures, where the rubber duck would fall out of tune with a temperature increase (i.e. from 25 celsius to 60 celsius). This can be attributed to the larger radiating element, where the rubber duck has the fine wire..

Cheers,
Bruce

Yep, I think that's what it basically boils down to. The apertures would have to exactly overlap to extract all (or would it be half?) the power. As far as I can see that would mean the two antennas would have to be exactly coincident in space. But anywhere the apertures of two antennas overlap, a little of the energy in the field should be extracted if there is any resistance in the receiving antenna termination (as there will always be).
End of thread I think?

>Somebody around here once quipped that it has about 3dBdl gain over a dummy
>load (the dBdl being defined as the gain over an isotropic Heath Cantenna).

The quip, of course, is really not very accurate. The gain can approach a normal dipole on the higher bands, and my finger-in-the-wind guess is that it will drop to about -10 dBd on the lower bands. I believe ARRL did a Product Review on it at one point.

The antenna can have advantages. The resistive loading tends to tame down the otherwise high SWR that could exist on some frequencies. I would, however, personally not use it; as a QRPer, I need every dB I can get. My wire antenna choice is a dipole, of any length, fed approximately in the center with ladder line, used with an antenna tuner. Purists will cringe, but I usually do not connect the ladder line to the balun in my tuner, but rather to the coaxial output (one conductor to the center conductor of the coax connector; the other to the shield of the connector). That way, I do not have to wonder whether the balun is lossy on some bands. In many cases, the loss caused by some of the RF being radiated by the feedline will be less than the loss of a badly mismatched balun.

That's what I thought..... it doesn't make much sense to have two shields if they both carry the same current!!! Go get a good physics 2 book to see why if you don't believe that!!!

Hi Tom,

For a few years now I have been thinking about putting together some sort of phased array for receiving on the lower HF bands (160m, 80m and 40m). I have seen design plans for arrays of phased loops with the phasing accomplished using feed lines of different lengths. The arrays I've seen are limited to one or two bands and have somewhat limited bandwidth within a band. They are also somewhat complicated to construct. They would, however, fit into the somewhat limited space I have in my backyard (~120' x 60').

I am thinking now that I may be able to construct an array that meets my needs as well as being simpler to construct and more versatile (i.e., multi-band, unlimited bandwidth) by erecting two small vertical elements (~10') and phasing them using the MFJ noise canceling unit.

I would appreciate if you would comment on this idea.

Thanks.

Bob

>--
>Crazy George</snip>

Hey bud, I've got news for ya..... I've worked as a Network
Admin before, and on of the major things that I've run into is
that often the CAT5 cables are not connected properly (thus
defeating the purpose of using STP or UTP cable). If you are
sending signals along CAT5 (CAT5+,CAT6,CAT4,CAT3...., ETC.)cables
then they should be paired. For instance in the Ethernet specs
(802.1-802.3) UTP with matched pairs is the minimum called for
data-carring cable configuration. (For instance in 10/100Mbit
copper wire UTP/STP Ethernet orange-white/orange [RX+/-] and
green-white/green [TX+/-] on a patch [computer-to-hub/switch]
cable are spaced out into the series
"orange-white,orange,green-white,blue,blue-white,green,brown-white,brown"

so that the RX/TX pairs remain intact. This is pretty
standard.) Obviously, if you use standard (poorly shielded)
equipment, properly grounded STP is worlds better as far as
intermod (external to the network) and packet loss (internal to
the network) are concerned (less common-mode garbage).
Also, if your computers are making RF noise (quite likely), then
you should start to demand PFC (Power Factor Correcting) power
supplies be shipped in all of you equipment (they make much less
RF noise--Rick, K1BQT & I carried out a test which confirmed
this; and they are safer because they draw less current from the
mains--and spit less back onto them also). One of the biggest
problems in the computing industry is that computers have
horrible power supplies in them. Also, as the clock speed is
ramped up the dV/dt inside of the microchips increases (nearly
exponentially--hence low-voltage BiCMOS chips these days in
almost everything) and thus two things happen: more power is
dissipated as heat during the switching phase of the internal
transistors, and more RF noise is generated by poorly designed
(not paired & properly terminated/balnced) circuit board/internal
microchip tracks.

In any case, so long as the cable (rg-58 or otherwise) is
connected properly _on_both_ends_ you should not be getting any
interferance from anything--period (except for what your
antenna--which is designed to receive--picks up). SO, the moral
of this story is to make sure that your transmission lines are
properly connected & that they are well designed.

Thanks to everyone for your replies. Let me elaborate on why I asked the question I did:

I'm an SWL who is studying for his ticket. I have the opportunity to buy some used equipment from a neighbor: Kenwood TS-570S, A99 & Hy-Gain 18V-S. I have a 70' random wire & MFJ-16010 random wire tuner (which I don't really need for my Drake R8B.) The Kenwood tunes up on ALL bands with the random wire tuner, how can I test the efficiency? (With the wattmeter on the radio measure efficiency?)

OK, I believe that the A99 is a great 10M antenna, obviously that's where I'll have to start. But I've also seen that the Hy-Gain 18V-S tunes up well on several bands and seems to work almost as well as the neighbor's dipole on 40M. However I don't have the yard to utilize a dipole, antenna needs to be somewhat hidden. Have had no complaints about my random wire, though.

Can set up A99 or Hy-Gain 18V-S when I use it and take it down when I'm done.

The neighbor also has an Alpha Delta OutBacker & tripod but it is pricey. Do they work well? Again, will the wattmeter on the radio measure efficiency?

Thanks in advance for your new replies.

Bill---there is another side of the story....I've also "been there and done that" and am totally satisfied with my B&W as it gives me the ability to work anywhere between 160 and 10 without tuning. For MARS operators that's a good deal as some MARS frequencies are not adjacent to the ham bands. Sure, I know and agree it's NOT an optimal antenna; it will not outperform a tuned dipole but it's close enough for government work. As long as people realize that the degraded performance is the "cost of doing business" to get the wide-band capability then no one should be disappointed. For me it works great on 75m and the MARS freqs just above 4 MHz; also gives me access to the WARC bands that I don't have on my TH7DX.

Source record: 175267

I am in the process of installing a transmitter which is designed to communicate primarily with aircraft. In a case like this does it make more sense to use a 0dB omni antenna as opposed to a gain antenna in order to better cover the air?

I don't know a whole lot about coverage patterns and plots, but by looking at them it seems to me that most commercial UHF antennas don't radiate up from the horizon very well.

Can anyone shed some light on this for me please?

I have a copy of that book, and do not believe that it is presumptuous and condescending. I just selected a page with "scannable" formulae and OCR'ed it. It is appended to this post. If you would like to select a page that you feel is presumptuous and understanding, I will gladly post it here, too. If one is interested in just the questions, they are available from a number of sites, including the ARRL web pages.

I am curious; why do you think ARRL not want not anyone to pass the test?

> I am unaware of a Gordon West League. How is it that our national
> amateur radio organization can not provide more helpful study material
> then a single individual?

Gordon's material is tailored, for the most part, specifically toward passing the tests. ARRL's study guides are tailored toward teaching the concepts that the test material represents. ARRL did finally bow to public sentiment and published more concise Q&A study guides. The League also publishes video study guides, although I don't think all of those are ready for the restructured exams.

> In 1993 I wrote the ARRL asking that very question. I presume they are
> still drafting a reply.

I would presume that the question was asked in a way that made it appear rhetorical. Part of the reasons there is a wide range of study guide material, from questions-only to Q&A to the more "formal" study guides is that there is a wide variation in the way people like to learn. I am glad you found one that works for you.

It will work well on 10 thru 17 meters (surprisingly well for a $40
vertical). You might be able to match the lower bands but with poor results,
even on 20.

Hi Dennis!

I've talked with alot of hams claining that the A99 (a GREAT deal ($40ish) and easy to setup NO GROUND PLANE vertical designed for use on 10/11m) works on 10-12-15-17-20 meters. The lower the band, the worst they claim it works, but one fellow claimed he worked 40 or 50 countries on 20m.

I suspect simple dipoles would work better and for 15-17-20m do not require much wire and/or room at all.

I have a 5/8 wave ground plane vertical on my roof, and before I got the tribander I had good result on 10-12-15 and really poor results on 17-20m.

I was thinking it would be nice if they came out with an A99 like antenna that simply screwed together and worked on the other bands without a tuner.

Perhaps you come from a place where everyone knows everything.. The
land of Luke Skywalker and Obie Wan.. here those of us that aren't as
"enlightened" as you ask questions. As well, we read the questions
carefully before we answer....

>As I say, how will the guy who asked know who is giving the right answer?
>Some of the answers might just be completely wrong, but look plausible.

The question was about antennas.. and later clarified to point out
that it was for SLOW SCAN TELEVISION. Last time I checked, IN
AMERICA THAT IS, slow scan television was not used to control aircraft
in any manner. You make it sound as if I asked how to do open heart
surgery. Calm down a bit. The question was about ANTENNAS, Not
about building a control tower at JFK or LaGuardia..

>I do hope that peoples safety is not involved in any way, given the way that
>it appears that people seem to be more willing to sue if things go wrong
>these days. If an accident did happen, I wonder what would the attitude be
>to the defence "Well, the people in rec.radio.amateur.antenna said it would
>be OK"?

An accident? People's safety? Are you actually reading these
messages or are you just spouting off to relieve internal pressure?
I'll say it again, slowly... "SLOW SCAN TELEVISION"... Not an ILS at
an airport. Lawsuits? What?!

>to my self training. I certainly wouldn't like to give advice on aviation
>communications without some form of indemnity insurance, and the relevant
>professional training, and I'd hope that even a private airfield wouldn't
>expect that equipment installation was being carried out by unqualified
>people. Especially ones that appear to be reliant on advice given in a
>Usenet NG!

Reliant? Airfields? I've just searched around for the thread you
appear to be dissecting but alas I've not found it. Indemnity
insurance? My god man.. people like you are the reason lawyers have
work. If everyone was so afraid to ask questions, and people were as
afraid to answer as you seem, Amateur Radio would not be what it is
today. A newsgroup is a place to field questions, and give answers.
Nothing says I have to believe, or even execute for that matter, every
tidbit which I receive on here. I take them all in, evaluate them for
what they are worth, and apply the information which I deem useful.

As well, I consider previous posts from the same writer as to how credible they seem.

>What happens if it's something for peoples safety whilst flying and it's not
>right? At best someone is inconvenienced, at worst..... Well, like my 11kV
>switchgear point, let's not even think about it.

What happens if you were to read the messages? Hmm.. perhaps you would know what you were talking about? I'll quote myself, "The setup is being installed to receive slow scan TV pictures from a Civil Air Patrol aircraft of accident sites and disaster areas".. the only transmit part of it is to say "Got it".. So it's not for their safety, and I promise I won't say something like "Clear for the ILS approach", and I'll strike the phrases "Descend and Maintain" and "Turn Left Heading 270" from my vocabulary in the hopes that it will let you get a good nights sleep... which it seems is something you desperately need.

And your switchgear point. Who said anything about electricity, and why must you make such an insignificant question about an antenna into such a monumental issue? If it will put your mind, and you keyboard to ease:

"I, Shane Reeves, do solemnly swear to call a professional electrical contractor should I ever need an 11kV switchgear installed in my 2 bedroom house. Here, in America that is, we be smart enuf to kno to do dis."

The double shielded coax I was talking about has the two shields isolated
from each other and is common in control systems applications. It is not
the same coax as a second shield wound directly upon the first shield
where the shields are not isolated from each other. I'm not sure which
type of double shielded coax is being discussed.

Ah, OK...Maybe the following will help a bit... I'm going to assume you can manipulate the formulas to get your particular unknowns in terms of the things you do know. If not, ask for specific rearrangements, I guess..

Resonance in an LC tank occurs for

2*pi*f = 1/sqrt(L*C)

To a good approximation (a percent or so for coils whose l/r is between about 1 and 4), inductance for a single-layer solenoid coil is given by

L(uH) = n^2 * r^2 / (9*r + 10*l)

where n is number of turns, r is coil radius in inches (generally taken to the center of the wire), and l is the length of the coil. A good rule of thumb is to wind the coil with turns spaced two wire diameters turn to turn, for good unloaded Q. You'll run across people saying that formula doesn't work for very small coils, but the inductance of a coil really does scale exactly with linear size. Scale all dimensions by 1/2 and the inductance of the coil itself will be half. But beware of self-resonance, parasitic capacitances, lead lengths, nearby shields or other metal, and the like.

For a coil with diameter equal to length and wound with turns spaced as suggested above, unloaded Q will be approximately

Q = 100 * d * sqrt(f)

where d is coil diameter in inches and f is frequency in MHz. Q increases somewhat for longer coils and decreases for shorter, though it's not a huge effect.

Inductance drops if the coil is put in a shield. Q drops similarly. A coil inside a cylindrical shield twice the diameter of the coil will have inductance about 15% lower than if it's unshielded.

For more complicated matching networks...I'd suggest you go spring for one of the ARRL books, or use one of the programs or spreadsheets that's been offered free here recently.

Cheers,
Tom

>And just how much additional loss would there be in say 4-5 feet of coax?

It would be an extra 150 pF to tune out. Perhaps not too important on 160-40m. On higher bands, it is likely that a tuner won't match some bands.

It is likely that a capacitance of the ladder line (with Ga 18 wire) to metal objects an inch away for a few feet practically won't matter.

Thanks to all who responded. In short, it should be an extremely poor radiator, probably not even useable.
I pose the next question: Use a Hamstick for 40 or 20 meters in place of the simple whip. Feed the base with an autotuner. Doesn't SGC do this? I seem to remember that they use a helical loaded whip resonant to around 14 MHz to cover most of HF.
Can any program model the radiation efficience of this setup? Further twist: Tilt the Hamstick at 45 degrees so I can get NVIS radiation, which is the goal for 75 meters, anyway. I think it will radiate both more efficiently as well as in a better direction (straight up). Comments? 73 de Jim, W7LS

Apparently both, which is why the thread has become somewhat confusing.

Some of you are reading this for the first time,
to others it is "old hat". Basically my story is
simple, Feb 1999 I paid over $5,000.00 For A
Mosley Pro-96-S antenna, The shipments were sporadic
and all the parts did not arrive until September of
99 at which time it was assembled (according to the
very shabby instruction manual) it was was raised to
70 feet and didn't resonate in any of the amateur bands.
SWR in the amateur bands were above 3:1 and higher in
most of the bands. Mosley was no help in trying to resolve
this problem and actually accused me of incorrectly
assembling the antenna. Any idiot can match color code to
color code and install screws into the pre-drilled holes.
Only problems were that not all the elements were color
coded correctly (most of the red elements were orange
colored while the remainder were red) the other elements
were color coded ok so with the left over pieces and a
tape measure the remaining orange pieces were found to be
actually part of the red element. The manual is so poorly
done that i had installed the 18" traps in the wrong location.
there was no mention in the instruction manual where the 18"
traps were to go, but did state that the shorter traps were to
be installed. because of the omission in the manual the 18" traps
were put in the wrong place. upon closer inspection of the itsy
tiny drawings in the manual i was able to discover that the small
traps went near the boom and the 18" traps went toward the tips.
after counting the number of turns in all the traps and verifying
that they were in the correct position and pointing the correct
direction, still no working antenna, still no assistance from
Mosley. Mosley did add to the confusion when they sent me the
engineers
drawing of the antenna showing measurements for the Pro-96-S.
That drawing showed a big difference between what I had in my back
yard versus what was drawn in their manual and what the engineer
drawings
stated. Some of the elements were short by as much as 12" overall,
some
were too long by as much as 12" overall. Finally in Feb. 2000 Mosley
agreed to accept the antenna back for "warrantee repair" which they
have had in their posession for over 9 months now.
To this date Mosley has refused to refund the original purchase price
for the defective product, refused to replace the Pro-96-S with a
different
model that has shown to work correctly (without a request for refund

for the difference in price), Refused to accept my settlement offer of a partial refund of the purchase price and refused to return the antenna
which they say has been tested and found to be working perfectly unless I
sign an order stating that i will no longer say anything about this antenna.
In other
words, as I understand it, they are blackmailing me by saying, either I
shut up or I don't get the antenna back. Do i regret my purchase of this
antenna from Mosley, YES, but based on previous dealings with Mosley and
using and knowing about their other products I felt I was making an informed buying decision. I had been very satisfied with the products i used with the Mosley name. This product and this time around though, there was no support, a very shabby manual, and accusations from the manufacturer that anything and everything that was wrong was my fault exclusively. Mosley flatly stated that there was nothing wrong with the
antenna and in fact their web page states that this particular antenna was assembled and tested prior to shipping. there are a couple of flaws
in that statement for the sporadic shipping of parts could not have allowed Mosley to assemble and test the parts at their location.
The absence of screw marks in the pre drilled holes indicated that the elements had never been screwed together. I have spent an addition sum

of money by trying to resolve this issue through the use of an attorney
in Missouri. While he has been most helpful, Mosley refuse to co-operate
and refuses to refund or return the product. i cannot afford to spend more money on this dead horse and cannot sue for attorney fees so the legal part is over.
one note of interest at this point is that Mosley did agree on 2 separate
occasions to refund the purchase price, once in november 99 when i first
had the problems. At that time I still had trust in the Mosley Name and
refused the refund offer because I wanted "multiple mono-banders" on one
boom. The other instance of a refund offer was when Mosley requested that
all material I had posted be removed from the internet and I agree to sign
a "gag-order". i requested that all information be removed from various

web pages and it was removed. Mosley immediately retracted their offer of a refund once i had complied with the 1st of their two conditions.
I will be glad to answer any questions you may have.
I will be glad to entertain any ideas you may have on how to resolve this situation with only one exception, I will not give up my right to free speech.
Do i wish to cause harm to Mosley, No, Not really, my sole intention is to inform others of MY Situation with Mosley's "Top of the Line" antenna.
Thanks in advance for your comments and if you know of others who may be considering the purchase of any commercially available antenna system, please advise them to do their homework so they won't end up in my situation. Tower Talk is a great source for information,eham.net is another, and of course most of the reflectors have something to say as well.
thank you for listening and if you want to forward this to others please feel free to do so.

I use a 270 foot horizontal (roughly square) loop up about 25 feet,
fed with ladder line. There's a balun at the bottom of the ladder line,
then coax to the tuner. Works great 180 thru 10 with a Daiwa
CNW-419 tuner.

Understand the mast is presently mounted to my wooden chimney frame
and therfore not grounded itself.

> Also you want all outside grounds tied together to keep all at the same

I just buried an 8' grounding rod near the antenna. (The location of
utility ground rod it on the opposite end of the house.) Any comments?

Where might I find one of these? I've checked radio shack, and several
local hardware stores (in the cable TV hardware section).

John,
Yes, they do in deed work. There are at least two under
construction here in the US, as well as a couple in Brazil and one in
Mexico. And there's a dedicated testing unit being constructed in
Britain for field strength evaluations and demonstration.

For a list of published literature on the subject, see the

I don't know how you came up with the 150 pf figure but, adding a
small section (4') of 100 Ohm line in series with 400 Ohm line on a HF
tuned fed antenna system will have very *little* effect. Possibly
there could be some tuning problem on the higher frequencies, but
that's more the result of adding 4 feet to the transmission line
length rather than the line's characteristic impedance.

I have used short runs of parallel coax for bring tuned feeders into
the shack for years and have never seen any ill effects for doing so.

>Thanks in advance for your new replies.

Hi Dennis,

The wattmeter will measure heat and radiated power the same way (this can be confirmed by noting how many watts are applied to a dummy load - all are going to heat and none to efficiency).

Don't worry about efficiency if you seek to improve it by 10-20% (not worth it). Worry about efficiency if all you have is 10-20%. But even here, this recommendation presumes you can determine that figure through instrumentation (not a good first choice) or through discussion in this group (far better, but you still have to separate the wheat from the chaff).

On review of the material that I did not quote, I would say that you are easily on the road to a reasonable solution and that efficiency will not kill you, nor will it's improvement bring significant results. Actually, if you look for further improvement, you might want to consider ground (RF) instead and not the sky-hook.

John,
To date, the 'CFA' antennas that had been built in AU have
all been scrapped. The stations returning to the original
antennas. Just from what I've seen, I think I'd pass.

Dennis,
The Alpha-Delta does work, and your right, they are not cheap. I don't know if I think it's worth that much.
The meter on the radio does not measure efficiency, but you can use it to get an idea of an antenna's efficiency. That sounds like a contradiction, but it really isn't. You'd be using the meter for comparisons.

"Sid",
I'll add my two-cents. I've used a few full-wave loops
and am using one now. I feed it with ladder-line, through
a tuner, and can use it on all bands. In a comparison with a
1/2 wave dipole, I'd rather use the loop. Of course, that
depends on a lot of things and results may not be the same
at a different location...

I'm just wondering why your screwdriver is too "fragile" for banging around off pavement. If it is properly installed, braced somewhere near the center of the bottom mast, it should be OK. It would be the whip that would take the beating, not the screwdriver unit itself.

As to efficiency of the whip/tuner combo, I doubt you would get much satisfaction from that.

I guess any antenna "works". How well is another question, and the evidence from the present installations in Egypt hasn't been terribly convincing. In over ten years, the inventors have yet to convince any but a few remote broadcasters that the antennas are a viable alternative to their standard tower systems. Independent measurements of one antenna in Egypt shows remarkable field strength if one makes certain assumptions about the ground quality. But it appears that even a very inefficient antenna could produce these strengths if, for example, there were a high water table or significant radiation from the feedline. But over all these years and despite the eagerness of the inventors to sell their system, to my knowledge (Chris, please correct me if I'm wrong about this), no A/B measurements have been made between a cross field antenna and a simple vertical radiator from the same location. This, in my mind, should be enough to trigger a good deal of skepticism. Quite a few people are awaiting results from the new sites under construction. I heard that one was being built in England, but wasn't aware of the others. Where are the installations in the U.S. being done, and when are they expected to be completed?

Jim Wier, a regular columnist for a popular aviation magazine, teaches this stuff for a living and is your best resource. And, I believe Jim is right about needing a General Class Commercial Radio License to set up aviation radio sites (you don't need one to set up radios for the cops or the local radio station anymore, but you do need one when dealing with communication involving anything large and licensed that flies through the air). A ham ATV link, on the other hand, is just that--and doesn't fall under FCC rulemaking for the Commerical Radio Service. However, the aircraft's pilot in command may veto your plan if he or she perceives a threat to safety created by a ATV transmitter working on board the aircraft (concern need not be rational--the pilot is the boss, period). Am I wrong??

Cecil:

I and the people I used to work with always referred to that as Triax, and I believe the connector manufacturers who make suitable connectors also call it Triax. Double shielded, as RG-223, RG-214, and RG-177, normally take standard connectors, center pin and shell only, with no third isolated conductor. It gets really confusing when many in the government use Triax connectors for Twinax cable, for what reason I cannot fathom, since Twinax connectors are cheaper. Hmmm, maybe that's it.

Ir seems as if people are missing the point here -- the guy said that he
was doing this on an authorized CAP or ham band (that's why it made
sense that he was UHF instead of VHF, like civilian air band). I'm not
even sure that it would be illegal for an airport FBO operator to set up
a Unicom rig on their authorized frequency by themselves either...

What is the deal here anyway? I've never seen such a bunch of "frequency cops" or "regulation freaks" than in this thread! A reaction of horror when someone merely inquires about transmitting to an aircraft? Even when the band was stated as "UHF"? I'm afraid there is a "Roger Regulation" OCD syndrome going on here... Even still, it's no big thing: I've got an aviation handheld that we sometimes use to communicate between my plane and people on the ground using "multicomm" on 122.9 MHz during coordinated operations. Big deal.

I suspect you're overfocused on the hardware which is newbie SOP. Concentrate on getting your ticket, then do the 570 and ONE antenna. The 18V or put your existing wire to work and get on the air on as many bands as you can. Don't get wrapped around a lot of axles, "efficency" issues, yadda, yadda, just get a signal on the air and think KISS theory. 10m is a lousy place to get started because it's transient hot nature goes away and there ya are, stuck with 40 being the only band open and ya wind up wondering what the hell happened to ham radio. Let me count the times . .

As long as the radio equipment is type certified or stepped for A/C use there will not be a liability problem for the insurance carrier responsible for covering the A/C and occupants from risk. All equipment installed on my three airplanes are certified/stp'ed by a local airport avionics facility and FAA inspected for 1, reduced exposure to any personal liability and 2, for reduced insurance premium cost. If it isn't certified, it doesn't fly with me regardless. 73, Ed - N5NUG

The unbonded ground rod is better than none. Are you sure you can't run a solid copper wire through the crawlspace or basement to the rod on the other side of the house, or at least to the cold water pipe on the near side of the house? Make sure the cold water pipe is grounded to the earth somewhere. Mine wasn't because the main pipe to the meter at the street is PVC. So I used the coldwater pipe to "bus" the utility ground and my equipment ground rods. It was interesting to note that my electric stove's safety ground was connected to this previously unbonded water pipe.

By the way, use a fence post tool (heavy single ended slip pipe with handles) to drive the ground rod into the ground, a hammer might be tough.

I am not sure what device that you bought, but look at the ones Polyphazer and Alpha-Delta make. The gas protector tubes fire at about 80 volts to shunt the induced voltage from getting into the receiver front end. Most front ends have a coil or capacitor that will handle the remaining surge. A direct hit to a discone antenna might be more challenging, but most nearby strikes won't bother it.

It was announced last month that the joint venture of Hatfield and Dawson and duTreil Lundin and Rackley, two of the most prestigious MW consulting firms in the US, has been invited by the CFA folks to make comprehensive measurements of a test antenna being constructed in GB.

At last report, the measurement protocol has been designed and measurements will take place "soon". It is my understanding that the measurements will be made by or under the direct supervision of Ben Dawson. He bore primary responsibility for designing the measurement protocol with extensive input from the other engineers in the joint venture.

It is also my understanding that they have been assured by the CFA principles that they will be given full access to the antenna, matching/phasing equipment and transmitter during the testing.

There are at least 8 installed as BC antennae in Europe. In Italy at San
Remo one gives same coverage as old 1/4 wave with half the original Tx
power. Another proposed for high power LW Tx in isle of Man. Another
being built near Birmingham, UK for test purposes. Another in use in
Egypt for at least five years without problems.

Tom,
You can simplify you're predicament by going to http://www.radioworks.com
check into their 4:1 external baluns. lets you run coax from shack outside and
then ladder line from balun to antenna. You won't have rf in the shack and you
will put out a decent signal with little physical or mental effort. My favorite
mode of operation!

3667. Re: Crossed Field Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-07 01:15:01 UTC
From: Christopher Trask <ctrask@primenet.com>
Message-ID: <90moal$j3d$1@nnrp1.phx.gblx.net>
Source record: 175215

On 6 December 2000 Roy Lewallen <w7el@eznec.com> radiated the following:

:
: I guess any antenna "works". How well is another question, and the
: evidence from the present installations in Egypt hasn't been terribly
: convincing. In over ten years, the inventors have yet to convince any
: but a few remote broadcasters that the antennas are a viable alternative
: to their standard tower systems.
:

<<SNIP>>

:
: But over all these years and despite the eagerness of the inventors to
: sell their system, to my knowledge (Chris, please correct me if I'm
: wrong about this), no A/B measurements have been made between a cross
: field antenna and a simple vertical radiator from the same location.
:

One of the papers I've listed does have a comparison, but I'm
not sure which one (I think it's the one from the Royal Signals
Institution, the British equivalent of the Signal Corps). I'm on a
business trip back east right now, but when I get home I'll look and make
certain. I don't want to misquote anything as this is a highly volitale
subject.

:
: I heard that one was being built in England, but wasn't aware of the
: others. Where are the installations in the U.S. being done, and when are
: they expected to be completed?
:

Exact details, I can't say for now as per the reasons given
above. I do know for certain that a major contractor for broadcast
antennas here in the US now has an exclusive contract to install CFA
antennas in the western hemisphere. As with all such things, providing
information for the general public is not a very high priority.

I try to keep as informed as possible on this, especially now
with all of the new installations popping up. A couple more in Italy
this year. RAI seems to like the design, as does a private German
company. The new installation in Britain, not associated with the
Isle of Man installation, is solely for providing the measurements
and comparisons that everyone has been demanding, and this will be
under controlled conditions so as to erase any ambiguity. Given the
amount of controversy surrounding this, I would say that the demo

installation is long overdue. Better late than never.

To all who responded:

Thanks so much for all of the useful information!

It looks like I'm not the first ham to encounter this predicament!!

It seems that I have variety of options here....

I'll probably start off with the parallel coax idea (it's the leaset expensive and I have some short pieces of good coax lying around....) If that doesn't work I'll invest in a remote balun. Either way I am determined to get some wire in the air!

Tom

>bands.

Why do you consider the coax to be a capacitor? In this application, is not a capacitor; it is a transmission line.

It is as probable that the addition of the coax will actually improve the matching situation on some frequencies as it is that it will hurt.

In other words, the impedance seen at the input of a random-length, random-impedance transmission line feeding a random-length dipole, installed at random-height, operating on a random frequency is a crapshoot. Four feet of coax isn't going to make it any messier than it is already. And it certainly isn't going to introduce any easily measurable loss.

You are creating the opportunity for a ground loop which is often
evidenced by a persistent hum or buzz in your audio that you just
can't seem to get rid of. Other problems could follow like burnt out
ground traces in your equipment's circuit boards.

>that Cecil's advice would make any sense if this weren't true?

In RF applications, the second shield does nothing at all to eliminate
common mode current, no matter what name you hang on it.

As Roy and others pointed out, the most it can do is add a little
extra shielding.

In applications where the shield is NOT several skin depths thick,
such as systems carrying very low frequency energy or responding to
very low frequency energy, the extra shield thickness can be helpful.

In broacast audio application, for example, an outer shield grounded
at only one end helps a lot but only if the INNER conductors have no
direct ground connections. If you gound the shield shield at both
ends, it conducts power line currents and induces them (becauyse it is
right against the other conductors) into the system.

>(As for rigs being dirty as far as RF goes, most of them are reasonable to bad.
>But, if you live next to a TV or cellphone installation--or near a lot of
>computers--the leakage of your rig will turn out to be quite minimal and
>insignificant when compared to common-mode pickup on improperly installed single
>or dual shield coax.)

That's right. If you install the coax wrong...no matter what
type....it will become a problem. Installion errors or flaws are the
single biggest problem, not the leakage through the shield in the
application being discussed.

Actually Butch, if I'm not mistaken, long long ago Mosley did offer
him his money back. At least that is what I recall him saying.

At that time, he preferred to bitch about the thing to the world
rather than take the refund. It takes two to start a pissing contest.

When only one person complains, and does so for a year or more, it
often means the problem isn't solely with the manufacturer. If Mosley
had a real problem, you'd be seeing hundreds of complaints....not just
one person.

Hi Mike,

That's not true.

The only CFA's out there that are "claimed" to be working are the few
owned by the people selling them, and none have FS readings anywhere
near that of a properly working vertical.

You've been reading too many of their sales picthes, and not enbough
of the reports.

At the NAB show, they admitted "10 dB down" wasn't too bad for a small
antenna like the CFA.

Hi Greg,
First things first--yes you will need a liciense of technician level or higher. Now about data transmission--there are many ways to accomplish this, and what would seem most elementary to you as far as data transmission is concerned isn't really that simple in the RF world. What do I mean by this? Well first off, I assume that you are familiar with the ins and outs of TCP/IP. Now imagine being constrained to 1/4 Watt and 9600 baud (about 9600 bits-per-second--including error checking--on a good day). Can you make this leap? The fact of the matter is that you are going to have to pick up an entirely new point of view about data transmission, about how much bandwidth is reasonable bandwidth (28.8Kbits per second [telephone modem protocol] is still experimental & unreliable at best over RF--because of how it works), about how much draw (power-wise) is acceptable for an embedded payload--basically you have no idea how difficult this will be as it sounds in your post.
Go get the amatuer radio books from your local bookstore or RadioShack. Read them. Go out on the internet and learn more about packet radio. Look up information about power supplies (batteries in your case) and how much the computer you plan to use will draw. Also, this will NOT BE CHEAP!!! (Unless somebody will donate the equipment.) Decide if this is what you really want to try (or if you can settle for some out of the box solution--and deal with its restrictions--see www.cicuitcellar.com for more info on these). Then re-post (or e-mail me) and we can discuss the full ramifications of the project that you have proposed here.

I've had a 40 meter full wave square horizontal loop for many years now.
It's up about 25 ft. fed at the corner on the end of about 15 ft. of coax.
It seems to work well on 40, 20, 15 and 10 meters. But, I do need to run it
through a tuner.

I built a 40 m model of the EH CFA antenna that was featured by one of the presenters at the last NAB event. I installed it on the roof of ARRL HQ. I asked AA1DO to show up late for work and, at about 9:00 in summer, we compared the signal strengths between the antenna and the inverted vee installed about 20 feet higher, hung off of the tower. The invee was consistently 4 S units better than the CFA antenna.

What would be useful, I think, would be to install two of them at the same height at about 100 meters horizontal separation. One could then measure the path loss between the two antennas, and compare it to the predicted loss, either by the formula, loss=-27.55+20logD(meters)+20logF(MHz) or to the loss predicted by the near-field calculation in NEC for vertically polarized infintesimally small dipoles (lossless).

What was interesting about the EH antenna is that when the inductance was adjusted to resonance, the antenna did indeed exhibit a 50-j0 ohm feed point. Minor variations in inductance changed the impedance by adding inductive or capacitive reactance, but also by significantly lowering the R component, all as measured using our MFJ bridge.

Mike,

Had a R71a for many many years. Great receiver!

Heard good things about the carpet loop but never tried one. It is the first link, the others are decent links with varied information. Last link is pretty cool!

Mr. O'Neal is caught in a lie.

Readers of this NG will recall as a matter of FACT that O'Neal stated that the fractal quad he built was superior. This -3dB to that Yagi of the same size would require a very small 2 element Yagi with 6 dB gain!

mR o'nEAL: If you have data that shows my measurements to be wrong, then publish them in a magazine or journal. You will not ever manage to undo this lie of yours.

As a quality assurance rep, having worked for several companies, I would have to agree that Mosely personnel are definitely making some bad business decisions here. The primary one, of course, is they still have $5,000 of a customer's money and are not acting in good faith to make restitution.
Personally, I would refuse to represent any company that used this sort of tactic against its customers. I requested and received sales literature from Mosely and was considering the purchase of one of their antennae. I am not going to entertain that thought any further.
When one of our customers makes a complaint, we file an 8D report within our quality department that requires the problem be contained and that the issue must be resolved to the customer's satisfaction within 90 days. Any outstanding 8D's are presented before the managers of Quality, Manufacturing, Sales, and Shipping for review. The customer may at any time request a visit by me or my highest level manager if they are not satisfied with telephone conversations.
I make a lot of those trips and always act in good faith to please the customer, having confidence in the company that I represent. Briefly, I would refuse to work for Mosely and represent their products. Johnny

I tried a long loading wire from the top of trunk mounted antenna to the hood/front bumper area one time, but found it worked very poor. My wire was way too close to the car metal. I would think you would want a tall front antenna to keep the wire up off the car a good ways to work. Also in a way I think it would be best to have an insulator high up on the front antenna to keep the high voltage part away from the metal. Mainly for the same reason. So the front antenna could be a "dummy stick" and just a support. I'm trying to decide how I want to mount a mobile in a truck I've been driving. It's no sweat right now, as no camper, but I want to put a camper top on it before too long. So that really ruins things as far as good antenna mounting. Or to me anyway. I'll probably still mount on the bed rail somewhere I guess. Either that or use a cab mount up on the door/window pillar. But, I'm not too keen on possible cab damage, so I'll probably go with the bed somewhere. On my car it's on the trunk behind the back window. Pretty easy. MK

Actually, the cb antenna shouldn't be all that bad. Good for the higher bands I would think. If you only fed the center pin to the radio and left the shield floating it would even work low bands ok. Sure, you may not have the signal level as other antennas, but the S/N ratio should still be about the same unless you need a certain pattern. As far as rcvr's usually for me about any old wire will do, the longer the better. Run a magnet wire all along the ceilings around the house. That should work ok. Also a small tuner can help sometimes to get a better match on certain bands. Any old cheapy L / random wire tuner would do. Also you might look into some of the active antennas, although I've never use or needed these. Seems kinda like a waste of money to me for normal hf listening when a wire will usually do. MK

Assuming a supergain antenna cannot create energy, the only explanation for "2 to 3 S-units" (12dB-18dB) gain over a reference tribander is a narrowing of the beamwidth. Seems impossible for a two-element beam to narrow the beamwidth that much. Maybe that reference tribander has water in its traps? Your idea for a reference dipole at the same height is a good one.

That is a free space number. For metal antennas, that number must be reduced by a certain percentage because of the difference in the speed of light in free space VS metal. For a wire antenna, the reduction is about 5%.

Not my experience over many years at all, been there, done it. Always got much better signal strengths and s/n ratios with outdoor antennas particularly on the low bands and particularly when I got 'em up at 50' and above. I'd suspect something was not right with the 70' wire.
>

> How strong is 18-gauge wire - much less 26-gauge?

Don't have the actual break strengths but plenty strong enough for reliable 30-40' runs into trees with ice. The big trick is to leave plenty of slack in the wire between "supports".
>

> The last straw for me with that 14-gauge longwire was when an average-size

You are not gonna hear JAs on 80 with an indoor slinky antenna like I can with outdoor sneak wires.
>
An average size tree branch will take out a $1,000 beam, too. All antennas installed under conditions which put them at those kinds of risks are considered expendable, gets knocked down,, ya put it back up, that's just ham radio SOP. I have a 475' of insulated stranded #14 soft copper house wire strung thru seven big trees at my brother's place, been clobbered by two hurricanes and it's still up. Yeah, some branch will eventually land on it and I'll have to fix it.

Hi Tom,

Thanks for the reply.

I am wondering how you load your 20' vertical antennas. Specifically, what
do you use to guide you in determining how much series resistance and
inductance to use?

Hi,

I just purchased a handheld for a backup in the cockpit. When I use it at home to listen to transmissions, I only get the aircraft and not the ground based stations (Air Traffic Control). I would like to build an antenna for the roof to try and pick up ATC as well. I am no way as techincal as most of you on this board, but I am fairly handy, have a physics degree, and enjoy tinkering (and love climbing on the roof).

Can anyone help get me started to build something like this?

Thanks,

Paul Loring

Bill Turner wrote:
"Also using the longest stinger possible will help a lot."

Similar antennas on both ends of an ionospheric 75-mile path in southern Florida (good ground) were used at 3 MHz to get comparative data for several antenna types using the F2-layer.
These data were collected for the War Deparment`s "Electrical Communication Systems Engineering". A table gives signal level, noise, S/N, and power needeed for equal S/N. I`ll give only the relative received signal db:

Horizontal half-wave, end-fed, 7-ft-high=0db.
Horizontal half-wave, end-fed, 30-ft-high=+21db.
Horizontal half-wave, center-fed, 30-ft-high=+21db.
Sloping half-wave, 5 to 30-ft-high=+12db.
Sloping quarter-wave, 5 to 20-ft-high=+1db.
45-ft horizontal top, 35-ft downlead with 80-ft counterpoise at 5-ft elevation=-2db
15-ft tuned whip with crow foot counterpoise=-38db.

This 75-mile path requires high vertical angle radiation for the short skip. There was a footnote regarding the horizontal half-wave antennas at 30-ft elevation. These were measured using a 150-mile path. No explanation, but 30-ft elevation at 3 MHz won`t concentrate the signal at lower angles for DX.

My money would be on the half-wave at 30 feet. I`d avoid the 15-ft whip no matter how good my tuner or ground were, unless I had a mobile installation and could not use the half-wave horizontal. The sloping half-wave isn`t half bad, either. The surprising flat-top sorta stunk. A Signal Corps kit for the SCR-188-A radio was used as the flat-top. This radio operated at 1.5 to 12.5 MHz and tried to get either !/4-wave or 3/4-wave resonance in its inverted L-antenna with counterpoise.

The antenna elevations will scale for other frequencies but the ionospheric behavior is different.

Best regards, Richard Harrison, KB5WZI

> Has anyone built a CFA "crossed field antenna"
> What is the typical radiation efficiency and bandwith for a small 160m
> operating antenna?
> Are they any better than other antennas?
> Do they really work?
>

The Cross Field Antenna (CFA) is an electrically small antenna and operates under the same laws of physics that all electrically small antennas do. All electrically small antennas "work" to some extent in that they radiate some portion of the energy delivered to their input terminals. The real question is what percentage of delivered power is actually radiated.

Additionally, the CFA and all other electrically small antennas can be impedance matched to 50 ohms at any single frequency. Usually, this impedance match is constrained to a very small bandwidth and is very sensitive to minor changes in the antenna structure and the surrounding environment.

The question of whether or not the installed broadcast CFA antennas "work as claimed" appears to be an open issue. To anyone who states that the CFA antenna works as claimed by the inventors, I ask the following question - Have you personally witnessed testing of these antennas and personally verified the level of power delivered to the antenna and personally verified the measured radiated field strength? I have spoken with one of the RF engineers that traveled to Egypt to verify the installed CFA performance. He indicated that his group was able to measure field strength but were never allowed to determine the power delivered to the antenna. I am certain that those on the other side of the evaluation would have a different story. Since I would prefer not to draw conclusions based on one individual's statements, I think its important for anyone stating that the antenna works as claimed to identify the basis upon which this statement is made.

There are also numerous issues surrounding measuring the CFA performance that need to be considered and identified when presenting measured data. For example, when the broadcast CFA is energized, are the original broadcast tower antennas still present? If so, the near-field energy created by the CFA will couple to the existing broadcast antennas and the "antenna" being measured is now an array consisting of the CFA and the original broadcast towers. This situation does not represent a true "CFA test".

Additionally, field strength measurements from the CFA must be presented as compared to a standard antenna with the same power delivered to its input terminals. I mention this because I have seen absolute measured field

strength data presented for the CFA with no relative comparison data. Field strength data presented with no comparison to a standard antenna is virtually meaningless because the measurements will vary as a function of ground parameters, terrain topology, multipath, and the presence reflecting objects near the CFA antenna.

Comparison data must be presented in evaluating the CFA antenna performance. Additionally, the antenna should be tested with no other reflecting resonant structures (like existing broadcast towers) nearby.

Just some thoughts ...

>this way?

Why would you suffer all of the grief of using ladder line, especially when
feeding an unbalanced antenna, just to "save" some imaginary dB?

If the inverted L/tuner has worked well before and you want to improve it,
unless you want to work 160, I would recommend you ditch the horizontal part,
use low loss coax and be done with it. It sounds like your run is only a bit
over 25'. If you want the to go all out, pick up some surplus 1/2" Heliax at
the next hamfest.

A 55' vertical isn't the best for the higher h-f bands, especially if it's
coupled closely to the supporting tree, but with the lousy "peak" of the sunspot
cycle might as well write them off anyway and worry about 80 meters.

> I do have over 3000' of insulated radials going to a few ground

Aside from it just being general knowledge, a cursory read-through of
the FARs and other aviation-related publications reinforces the notion
that SSTV has no current or planned role in the air traffic control
system in the USA.

Try a simple verticle dipole first to see how much signal you get.

Take a length of PVC pipe (cheap) and tape coax to it. Connect about 21
inches of wire connected to the center sticking up. Connect about 21 inches
of wire pointing down to the shield. Since you are not going to transmit,
lengths are not critical. See if you can hear ATC.

You can make a more permenant ground plane later if the signal is good.

Get a copy of the ARRL Antenna Book and look in the section on verticle
antennas for ideas on how to build a sturdy version.

>in its traps? Your idea for a reference dipole at the same height is
>a good one.

It's generally better to use a reference antenna with a similar pattern
to the one under test, so that any problems with the test range apply
about equally to each. Unfortunately a dipole is about the worst
possible reference antenna for *practical* tests because it has no
discrimination against stray reflections.

From that point of view, they're getting it right by using a reference
tribander rather than a reference dipole.

However, that doesn't eliminate the possibility that the reference
tribander itself isn't working properly. To do that, it would seem
better to check against two different tribanders (same size, different
make, different trap design). If they are both ones that have already
been measured in the K7LXC program, that also offers some possibility of
cross-checking.

Yet another sensible precaution would be to duplicate all the
measurements with the antennas swapped between the two towers.

Yes, it's a lot of hard work to get antenna gain measurements right.
That's why modeling is generally more accurate.

NEC-based modeling has been highly successful for a huge range of
different types of antenna - literally from dipoles to dishes and
beyond. Of course NEC has limitations, but the large user community have
pretty well identified those problems. At this stage of its development,
NEC doesn't have to prove itself against every challenger who comes
along.

If someone says that "NEC doesn't work for my antenna," I firmly believe
it's *their* responsibility to prove why not.

Ken,

It is impossible to build your own beam antenna. Being told such a
thing is possible is like taking a kid "Snipe" hunting. I don't know
why hams continue to spread this homebrew antenna myth but they do.
Antennas should always be purchased from companies like KMA Antennas.

But if you insist on taking part in this ancient ham radio farce, try
looking at these web sites.......

Good morning all,

It might be instructive to look at where these antennas are sited. Tanta, Egypt, is about equidistant between Cairo and Alexandria, the two major population centers, at a distance of some 50-60 miles. Flat delta terrain. San Remo, Italy, is a coastal location backed up against a major escarpment (very much like Monaco) with France at the top of the mountain. They broadcast in Italian. The Isle of Man is small, 277 square miles, or so with a major mountain in the center.

None of these sites require much in the way of antennas to be effective, especially San Remo. I suspect that the reason these antennas work (more or less) has more to do with what they are expected to cover, rather than any intrinsic technical merit on the part of the antenna.

I have acquired a second Hy-Gain Hy-Tower which I intend to phase with the one I have up now. I am very interested in hearing from others who have successfully phased two of these fine old antennas.

In the ARRL's "Vertical Antenna Classics" on page 72, there is a very interesting article by Peter Anderson, KZ3K on "Phasing Verticals with Continuous Phase Control." I am especially interested in hearing from anyone who has implemented this "steerable" phasing system.

Any tips or suggestions will be most welcome! Please reply via email.

Greetings from Yuba City,
I bought this antenna because it would fit on my lot, be suspended from the center by a support on my tower, and give me a replacement for my 160 meter antenna. It does not work on 160 except as a dummy load, a fact B&W doesn't like to admit--I have talked to them directly. They say it works on 160 if mounted in free space 80 above ground level. I doubt it but maybe you can do that and let me know. The antenna starts to lose its low swr profile at about 3.7 MHz and below that it rises rapidly to the point that only a really good antenna tuner will let you pretend it is working at all. On 40m and higher, it is a good antenna.
My situation is that my tower is behind my garage, and the antenna is at 40 feet (the maximum recommended in B&W's literature.) One side of the antenna therefore runs across the roof of the garage at about 25 feet average while the other just slopes down across the backyard. I am able to work to the east on 80 m with good results, but the antenna tuner in the IC-746 is engaged at frequencies below 3.7 MHz.
A load resistor and matching transformer (two separate elements) allow this antenna to radiate on the higher frequencies. I made one contact on 160 after first installing the antenna, and have had nothing since. If it were not for its utility on the higher bands, I would have gotten rid of it long ago.
A friend about two miles from me has an identical antenna mounted at 40 feet height across a clear backyard without obstructions. Using my MFJ 259b, his antenna and mine exhibit almost identical properties over the range of frequencies I mention here. So would most examples of this antenna, I suspect.
To give a short answer to your question, if you don't need 160, this is an acceptable antenna.

Hi Kevin...and lurkers.

I looked up the manual, and the "Principles of Operation" section is just a single page. Paraphrasing and condensing: The generator input feeds a short loop of coax to the "unknown" port. As close as possible to the "unknown" port is a pair of probes, one magnetically coupled and one electrically coupled to the through line. Those two probes feed the two ends of a loop of slotted line. Each probe appears to be terminated, presumably to prevent reflections on the slotted line loop of the signal from the probe at the opposite end. There are two front-panel adjustments which the operator makes to get a null on the receiver port, those being magnitude and phase. The phase adjustment (really a time-difference adjustment, but calibrated to read phase directly at 100MHz) is just the slotted line pickoff position (which feeds the detector port). The magnitude adjustment changes the spacing of the probes from the line, presumably increasing one while decreasing the other, though they never 'zactly say that. At any rate, the ratio between the couplings is variable.

Without thinking too carefully about it, I suspect the only two resistors--the ones that terminate the probes--are OK if you got a constant error, independent of frequency. If one of those was bad, you'd have reflections on the slotted line that would cause frequency-dependent effects, no? And in fact, there may be a mechanical adjustment to set the coupling ratio correctly, and that may be all you need to do. Comments (especially ones to make my thinking on this clearer) are most welcome.

Cheers,
Tom

i would suggest stacking atleast 2 of each to improve gain and actually 4
would be ever better and you will need atleast 160 watts
there is a lot of signal loss between the earth and the moon and back and
you will also need a good preamp
good luck

The CFA controversy sure is interesting. On one hand, for whatever reason, there is a real dirth of quantatative data. OTOH, if that 50 kW Egyptian station's antenna were badly inefficient, I think it would be pretty evident in the 49 kW of heat that would be radiated by the structure. Even if the antenna were as good as 10% efficient, better than some of the comparisons I have seen posted here, 45 kW would be lost as heat, and I think that 45 kW of heat would be pretty hard to miss.

All that I know is that I have duplicated two QST article submissions. In one case, I was unable to reproduce the matching arrangment, but did some expermintation that seemed to come pretty close. This one used a tapped autotransformer to obtain the impedance transformation, along with some Ls and Cs. I could find a number of combinations that would result in a 50-ohm match, but in no case did that CFA hear better than a piece of coax laying on the ground. The other one seemed a lot easier to tune, but was consistently a few S units below the reference horizontally polarized dipole, albeit over a short path.

I had seen one other study that, if memory serves, had been done by the British Army. In that study, at a point about a mile away, presumably by ground wave, the CFA was at approximately the same level as a relatively low horizontal dipole. Unfortunately for the CFA, the signal should have been a lot stronger from a short vertically polarized antenna than from a dipole, which radiates relatively little energy toward the horizon. I stretched NEC's near field calculation probably past its limit and it predicted that the field from an very small vertical should have been about 20-40 dB stronger than the field from a low horizontal dipole, at a point 6 feet above average ground, 1 mile away. (I am working from memory on this, but the gist of it is correct).

Among the several projects found at:

http://www.arrl.org/tis/info/antproj.html

are pdf's of several QST HF and VHF beam antennas.

Randy,

For 2m EME I would suggest a minimum antenna gain of 20 dBi, at least 1KW to the antenna and a noise figure of about 1 dB.

You can work some of the "big guns" (W5UN, KB8RQ, SM5FRH, F3VS, et.al) with less but that's about it. I have worked all of these guys using 1KW out, a HB 17 el, 3.2 wavelength Yagi, 180' of 1/2" Heliax and a 0.8 dB NF preamp (in the shack).

Before changing QTH, I had four of these Yagis and a short run of RG-17 and could hear my echoes about half of the time. I don't believe you are really EME capable until you can hear your own echoes.

Hi Tom,

I'm not sure I can add anything except reassurance of your descriptions. That is, because anytime I had to service/cal any of these instruments (speaking generally) the circuitry was just as simple as you describe. Also, your description of the theory of operation is right on as far as I can see.

HP always designed with first principles in mind and no bluffing. The simplicity of their designs were always a testament to the continued bullet-proof operation and rock-steady results.

As to w9cf's speculation about past abuse, I can agree that was a probability. I too bought my GR-1606 at a show and when I asked how well it worked the fellow sort of mumbled "fine" and looked away. It didn't matter to me later when I confirmed that the reference resistor for the bridge wasn't even in the circuit! Undoubtedly someone keyed down into the bridge and fried it. Simple resolution - much the same as w9cf speculates - replace the resistor. However, both w9cf and my seller appeared to be intimidated by "precision" when, as I said, the solution was simple when you consider first principles.

I have had to service/cal equipment where circuit components and layout mattered immensely (at least when you are measuring out to the third place or beyond), but standing back and considering the situation always lead to a robust and simple solution. Proving that the solution is effective can be a challenge, but even here, common sense prevails and provides equally suitable, simple tests.

Both your comments and those of w9cf give me every confidence that this bridge will be back in operation.

All is revealed,
Tom the philips headed screw closest to the TUNE knob on my MFJ 259 was slightly loose,and with downward pressure was showing very strange readings, nipped it up and all ok,
i must say in regards the R 8 .i have assembled quite a few commerial and home brew antennas, but for ease the R 8 is the leader,
as per the C/CRAFT manual.NEVER touched the antenna in regards tuning.
perfect out of the box. only 2 full S POINTS down on 10mtrs against a full size trapless tribander HB35C at 55ft.this antenna is mounted on top of a 15ft shed roof,and then again another 7ft to the tilt frame.
many thanks to all that replied
Kind Regards Dennis VK4SX.

First, I want to thank all the people for the replies. I do have a few more questions. You suggest "Stacking 2 of each". Do you mean stacking them in series or parallel to each other. Others replied that I need min of 20db gain, would "stacking" two add the gain of two antennas? Also to connect the two antenna to the same coax would i use a Y-connector??

Let me see if I understand if I "stack" 2 2MCP22 antennas each having 16db gain would that give me 32db gain??

Thanks Again?

Sure, and pigs can fly. Look at where the data comes from. The
supporting data all comes from...suprise!...the people trying to
hoodwink people into believing in something that they are
selling....that they can't or won't supply data for.

Ask yourself this....

Since that antenna has been around and available for nearly a decade,
whuy can't the owners or sellers point out an independent measurement
backing up their claims?

If it works like they say (which it can't since the theory itself is
nonsense) why are they selling copies of plans to hams on Antennex
instead of selling hunderds of them commercially?

Why is Antennex complaining about a lack of supporting results, when
they are making money off the thing??

Frankly, I'm amazed after about ten years of non-results they can
still find suckers who fall for their bolognia....but then I guess
people still buy magnetic pillows to releive headaches.

Thanks Guys,
The 135' L worked good when I had it up last year. I think that I will put the B&W in the garage and put up the L again. I do operate 160, so will run the full 1/4 wave wire for that band. Now I know that I can use a balanced line if I put up another dipole in the future. Gona use the parallel coax runs in the ground. Thanks again es 73's, Mike> WE0H.

Source record: 175026

The National Electrical Code
REQUIRES
that the electrode you made be bonded to the house
grounding electrode system, per article 250-50.
The size of the bonding jumper wire is given in
table 250-66 - the smallest is #8, and the actual size you
need will depend upon the size of the service entrance
conductors. Your #10 wire is too small. You must also
connect the jumper as per 250-70.

You don't have options in this area, other than those
contained in the code, if you want to be legal and safe.

When you stack another equivilant antenna you will get about 3db of
gain, better fb/fs and sharper pattern.

Stacking means one on top of the other. Then if you add two more you
put them beside the other two. Parallel feed.

I made an error in my earlier post. The smallest conductor
you can use to bond the electrode you made for your radio antenna
is #6 copper or equivalent, not #8. Also, I neglected to mention
that the references I gave applied to the 1999 NEC.

I'll add this: if you can ground your antenna to the existing house
ground instead of adding a "made electrode" (the ground rod you drove),
you avoid the conductor size problem. For example, you can use #8
aluminum or #10 copper and connect to the interior grounded metal
water piping, if available. See NEC article 810-21 Note that all
of this discussion is directed at grounding the antenna MAST and/or
metallic support structure and/or the antenna discharge unit, not the
antenna itself.

With 5 years experience as the manager for client relations, I, too, have been amazed by the reported conduct of Mosley Antennas. In a hobby like ours, where contact with other practicioners of the same hobby is the primary goal OF the hobby, and where nearly every such contact includes a description of the equipment in use, I am flabergasted!

There is a basic principal used in every dispute resolution: Save the money, or save the customer. It is virtually impossible to do both. Mosley, it appears, has invented a third: Steal the money! I cannot believe that you are without product or refund at this stage.

I appreciate your keeping us apprised of future events,

Kï¿½MB

Hi All,
Did a search on this particular antenna and did not come up with much. The 10 meter contest is upon us, and considered playing around with it. The orginal design was in QST circa 1957 or so. In short it is a bow tie dipole with a loading coil and link coupling to the feed. Anybody done this before with any results? One thing I find troublesome in the orginal design, the loading coil is 12 turns 1 inch dia. 3 inch long, but they short out the last 1.5 to 2 turns. Why? Apparently this was a very popular antenna in the 50's when we had ionspheric conditions that were once in a lifetime. Need answers fast cause the contest is about to start:-).

I've had good luck with an amplified active antenna, a Stoner Dymek
DA100D, with the 5 foot whip indoors, attached to a jrc nrd525
receiver. However, an outdoor wire antenna did substantially better.

I'd just putter around and see what you can get indoors by stringing
wire every whichway -- partly it depends on whether you are on the
ground floor or a 2nd or 3rd story.

Experiment, and see what sounds best. You really can't know until you
try a number of alternatives, and, after all, isn't that one reason
you mess around with radios, in the first place? 'T'is, for me :-)

I used a regular antenna analyzer to determine the resistance and reactance needed, but after the process was over I found that Eznec gave an excellent result on everything but the ground loss resistance present at the antenna terminals.

When the "gain" (signal level) was compared to my full size vertical, Eznec was very close.

I used enough inductive reactance to compensate the capacitive reactance of the verticals, and then added enough series resistance to get the feedpoint to 75 ohms, to match the feedlines.

The resistance "swamps out" the mutual coupling effects, giving me a wide VSWR bandwidth. Even with the swamping the sensitivity is much higher than my Beverages.

I use three top wires as a combination guy-line and loading hat. The 20 foot structure is self-resonant on 3.5 MHz, meaning a simple electronic switching system can make the array work on both 160 and 80 (by electrically adding or removing the loading reactance at the base).

For one Europe antenna, I have four 800 foot Beverages spaced broadside 350 feet apart. That array occupies a 1200x800 foot area. Quite often my four verticals spaced 330 feet broadside and 70 feet endfire beats the much much larger Beverage array.

The four vertical array always beats a single Beverage, every time.

Gary,
Sounds like the coil was used for matching. A tap 1.5 to
2 turns would appear to be where you get the best match.

You might want to check with the local FAA facility and see where the transmitters are located. Most of the ATC facilities are co-located at a site that may be out of range regardless of what antenna you put up. If you can give me your location I can look in the FAA data base and tell you if any of the facilities are close to your location.

This is going to sound pretty wierd, but I'm quite serious...

My annual pilgrimage to San Francisco comes up the week of Jan 14th. While standing on the Golden Gate last year, I saw the bridge differently - as an array of "potential" vertical antennas, just waiting for a transmitter to come along.

Well, this year I have a 706MKIIG and am contemplating taking it along. Assuming I don't get locked up on some sort of vandalizm charge, what might all of you think about the chances of this working?

Figuring out what would be good connection points for ground and the "driven element" will require some careful surveying on-site. I assume no one has actually tried this, but I'd like to hear if it has. I noticed several unpainted galvanized bolts where repairs had been done, which I hope are still there.

Thoughts and suggestions are welcome. (Especially if you know where the "blind spots" are - regarding the cameras that watch for "jumpers").

One idea was to drop a vertical downward and essentially create a vertical dipole, but that seems a bit tricky (harder to conceal) and potentially a problem as to the regs on "tossing" anything off the bridge.

I 'do' have a water faucet located nearby. I think I'll lift the
vinyl siding and connect the RG-6 male/male grounding block to the
copper water pipe with my #10 copper wire. This seems to avoid the
pitfalls generated by my 'additional' grounding rod.

> For example, you can use #8
> aluminum or #10 copper and connect to the interior grounded metal
> water piping, if available. See NEC article 810-21 Note that all

> metallic support structure and/or the antenna discharge unit, not the
> antenna itself.

I've yet to actually see an antenna discharge unit. I assumed it was
an inline device which was located at the input port of the scanner.
(indoors, at the end of the RG-6, at the point of connection to my scanner)

Now I think it's an inline RG-6 device which is 'best' located at the
antenna, and probobly as close to the male/male grounding block as
possible to enable -easy connection to ground-. Any comments?

Thanks for taking the time to repsond to my query.

I have a hard time figuring out why these companies do the things they do. I bought an Cushcraft R7000 + vertical and the 80 meter kit. Some of the parts were wrong, according to the directions. I contacted Cushcraft on my letterhead (attorney) and got a response. They promised to send the new parts. In spite of several follow-up letters, they never did. They even admitted that the kit had been updated, and mine was an old kit.

I could take more agressive action, but decided not to. Of course now I'm getting ready to install a tower and beam. It is doubtful that I would 1) buy another Cushcraft product, and 2) recommend the company to anyone else.

One person on this thread had it right, it a hobby where communication with other hobbyists is the essence of the hobby. Of course there are those who use the web to try and extort companies, but I cannot believe that my experience is unique. Once the company realized that the 80 meter kit was old, it should have been a done deal. Tom W6EIJ

Those of us old enough to remember the classic "Jeeves" cartoons by Gil in QST may recall the one where the auto is parked on the bridge and Jeeves is up tangled in the bridge cables with a roll of coax. The caption coming from the car says: "OK Jeeves, now let's try shunt feed, off center."

Many of those cartoons would not make sense to today's hams, but they were great!

First, I assume that you have the paperwork in order and license in hand?
Those in the airplanes (US registry and flying in the US) no longer require
a license, but those on the ground do.

Better cover?
Aviation radios are normally low power AM...5 to 12 watts. I think most are
in the 5 watt range

As many airports share the same unicom frequencies the idea is to have a
relatively short range. On a clear week end it's like one very busy party
line and with lots of squealing.

Towered airports do run a bit more power, but it's still relatively low and
they have their own frequencies and crews, or contractors take care of those
installations.
>
> I don't know a whole lot about coverage patterns and plots, but by
> looking at them it seems to me that most commercial UHF antennas don't
> radiate up from the horizon very well.

Most airplanes are either close to the horizon, or close to the station.

Ahhh...you don't find UHF at the small airports using unicom, or at least
I've never seen one. All the Unicoms I've seen..er... heard, were VHF.
I have the current AIM and FARs right behind me, but being lazy, I'm not
going to bother digging it out as I would on the aviation groups.

What did you say the reasoning behind setting up a transmitter was?

>
> Can anyone shed some light on this for me please?

I think this question will probably find lots of shedding <:-))

Quote from original post:
"I am in the process of installing a transmitter which is designed to
communicate primarily with aircraft. In a case like this does it make
more sense to use a 0dB omni antenna as opposed to a gain antenna in
order to better cover the air?"
End quote

No he didn't. He only asked about the antenna and talking to aircraft.
No mention is made in the original post about using CAP, or ham bands.
Actually no mention was made of using aviation frequencies either.

(that's why it made
> sense that he was UHF instead of VHF, like civilian air band). I'm not
> even sure that it would be illegal for an airport FBO operator to set up
> a Unicom rig on their authorized frequency by themselves either...
>
If the FBO is the Unicom operator and they have the paperwork taken care of
then yes, they may have unicom. But the airport may have only one unicom.
That it is used in the terminal building, in a car, or at the FBOs doesn't
matter as far as I've been able to find out.

It would be my GUESS that a simple 1/4 wave ground plane antenna
would give you a nice round pattern and work VERY well in all
directions.

I read this with interest an am disappointed with the answers and
replies. I was hoping to learn something.

One antenna NOT mentioned is an Eggbeater ot Texas Potatoe Masher.
Now I know these antennas have a horizontal pattern at the
horizon...but a circular patter overhead (30+ degrees?). Would
this be an option?

I'm still hoping I will learn something!

I respect Jim's knowlege...I don't care too much for his presentation.

You are legal in the airplane, but not out of the airplane.

Yes, it's done quite often, but it's still not legal, unless your airband
license covers the use on the ground, out of the airplane.

Which brings the question Jim, Does the installer have to be FCC, or FAA
licensed?
I don't know if the FCC license is available any more, but the installer has
to work for a FAA licensed facility and I think, like the mechanic, must be
licensed as well.

That is an idea. My main gripe with the camper "if metal" is the max current portion of the antenna right next to the metal. Yuk...Real antenna killer...I was gonna consider a cheap aluminum model, but maybe I oughta go plastic. MK

Yep, I agree if thats code. The only reason I stated that bonding might not be needed if far apart is I know from experience that this won't kill you if you take a hit. Myself, I don't have any connection to the electrical ground. Why? No readily available place to connect. We have no power ground rods etc. So I skipped that part. But I do tie into the water pipes and to the ground wires that run the perimeter of my yard. I took a direct strike on the mast and had no problems whatsoever. I think it's more important to have a really good ground at the base of the mast. This is whats really gonna do the dirty work of connecting the strike with the ground. In my case, I'm totally disconnected from ground, antenna lead-in, everything, when bad weather is around. So doesn't really matter how I connect the grounds outside. The one that really counts is at the base of the mast. But I would connect them all if you want to be in compliance with the NEC. In my case, the power line ground is the only one I'm not connected to.It's still at ground potential though. So far it hasn't hurt me. The proof was in the "{click-blamm!" lightning strike...g Many things were on in the house when it hit, including this puter. Nothing flinched at all. Actually, it was kinda interesting being 15 ft away from a lightning strike. But , I'm not keen on a replay..:/ But anyway, I agree, it may be better advice to ground all together. I do when I can. No, you don't want to do that. You want to stay with your outside ground rod. You never want to invite lightning inside the house. Also the water pipes may not be low resistance. Plastic parts, pipe dope etc, could eat your lunch. I would rather rely on a big fat ground wire that I can see. BTW, I see different gauges mentioned as far as NEC. Myself, I would use the thickest possible. At least #6. But saying that, if the ground and connection are low resistance, a #10 can do the job. I'd rather be thicker though to be on the safe side.

You want the suppressor grounded to the ground block/bulkhead which leads into the shack. "outside". I have a bulkhead outside my window. I don't use suppressors, but if I did, thats where they would be. MK

3768. Re: Crossed Field Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-09 09:37:27 UTC
From: Gray Frierson Haertig <gfh@haertig.com>
Message-ID: <3A31FD57.35F967A5@haertig.com>
Source record: 175070

At MW frequencies the initial measurements of CFA don't necessarily need to be done in reference to a "standard" antenna. To a first order approximation, the ground parameters can be inferred from the the shape and slope of the measured field strength data. This is especially true if the test site has reasonably uniform ground parameters out to 10 km or so. Abrupt ground parameter changes will likely be obvious from the data if not from casual observation of the surroundings.

If it is important to determine the efficiency (using the rather idiosyncratic definition of efficiency used by the FCC) down to the last dB, then there might be reason to do comparison measurements. However, measurements without a comparison antenna should be more than adequate to differentiate between the inventor's claim of efficiencies equivalent to a 1/4 lambda vertical monopole over a good radial ground system and the claims of the CFA naysayers who think reality is at least 10 dB shy of the claims.

Matters of terrain effects and reradiation are easily handled at MW frequencies by proper selection of the test site. Absent very large terrain features, multipath tends not to be much of a problem at MW at the distances from the antenna that field strength measurements are likely to be taken (1 km to 10 km).

The independent measurements that I am aware of that are soon to be made will be done at MW.

Of equally critical importance is having measurements of transmitted bandwidth. I believe these measurements are to be made as well.

At frequencies of interest to hams (other than the new LF frequencies), a somewhat different protocol should probably be used for many of the reason's Steve elaborated on. Since much, if not most, ham communications is done with sky wave rather than groundwave, determining the elevation pattern (coupled to the efficiency) of the antenna will be of great interest. Unfortunately, making truly meaningful measurements at HF is almost impossible, however with some attention to detail it should be relatively easy to determine of the CFA offers any great advantage over any electrically short monopole.

Gray

3769. Quad experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-09 11:39:45 UTC
From: "David J. Windisch" <davidw@copper.net>
Message-ID: <mSoY5.351$XY.7232@newsfeed.slurp.net>
Source record: 175064

I made a 20M sorta-quad by hanging a 35ft catenary wire connecting the ends of the 23ft trapped driven element of a Mosley TA34XL. It looks like a 'curvy-sided' triangle resting on its point.

It gets outta the back garden and seems to have a figure-8 pattern. Feedpoint Z went up according to my hf slotted-line (hard line with access-slots to the center conductor. Next time, I'll build it out of al tubing and a section of al gutter for easier access). Too much rf 'round here for analyzers

Haven't tried the next (logical?) step of putting a catenary on it for 10M. Maybe later today. I think 15M is outta the question cuz of the trap design.

How do I model this thing with EZNEC3?

TIA. 73, Dave, K3BHJ

Reg:

Re: Number of humps and tuning ease of lossless coupling circuits.

In general....

the number of "humps" in the "passband" of a "lossless coupling network or circuit coupling a purely resistive source to a purely resistive load will be a function of the number of independent lossless elements [L, C] in the circuit. Or more specifically the number of complex "poles" that the circuit produces. In the cases of even and/or odd order circuits [even number or odd number of independent lossless elements] the number of possible humps has a somewhat different character, for in the odd order case at least one of the humps, if present, must occur at DC and not in the passband.

Of course, depending upon the "damping" of the overall system there may be no "humps" or only one, or several, etc...

Some generic examples of this are: The Butterworth filter in which all of the "humps" are coincident and only one hump appears at the center of the passband. The Chebychev filter in which all of the "humps" are equidistant and spread out evenly [geometrically] throughout the passband. etc...

In general for high order lossless coupling networks, it would be impractical to "tune" them manually and these kinds of filters are always designed [aka tuned] by computer algorithms today. One would find many minima if attempting to adjust high order lossless coupling networks by hand. I've tried this on filters up to the 24th order, heh, heh. Can't be done!

On the other hand, that is generally not what ham transmitter output filters/tanks are all about, heh, heh. i.e. they are not "high order"

A simple output "tank" has but two lossless elements, an L and a C and generally would only have one knob [on the C] to manually adjust, hence one would find only one unique minima or operating point.

A PI output coupling network has three lossless elements and, since it is of odd order, will have only one "hump" in the passband, the other "hump" has to be at DC for mathematical reasons and is no interest to the ham operating the transmitter. But the PI coupling network can have two knobs [one on each C] for tuning. And so , one can find more than one setting of the tuning knobs to give a minima or tuning point. Each such setting corresponds to a single "hump" in the frequency response, but a different "loading" or coupling factor.

Now for a PI - L there are even more lossless elements and consequently more potential tuning knobs, and so... there could easily be several different settings for optimal tuning, unless...

the circuit is set up in such a way that the tuning "ranges" of the adjustable elements are suitably constrained by the original designer.

This is what I believe to be the situation in the commercially available ham transmitter PI - L designs. i.e. it is theoretically possible in such a circuit to have several "minima", but the ranges, values and placement of the tuning controls are such as to "almost" guarantee that the "tuner upper" will never encounter the "other" humps.

Just my opinion...

-Peter K1PO [Old guy who used to be a professional high order lossless coupling network designer.]

Program MIDLOAD analyses performance of a short
centre-loaded dipole fed by a link winding over the loading
coil. Advantage of a link coupling is that either balanced
or unbalanced feedline can be used over a range of
impedances.

Disadvantage :- only one narrow frequency band.

Download program and run in a few seconds.

Peter O. Brackett wrote:

> Of course, depending upon the "damping" of the overall system there may be
> no "humps" or only one, or several, etc...

In PA pi network design, it is always the practice to assign a value of loaded Q (the damping factor), a value of plate load resistance and a load (50 ohms). Under those constraints, the L and C values are unique and there is only one "hump". This is at least true for the pi. An examination of Eqs 17 and 18 on page 13.6 of the ARRL Handbook, 1995 or later editions, verifies this. Eq 25 on page 13.7 also uniquely determines XL, after which Q1, Q2, C1 and C2 are uniquely determined. Mathcad and Radio Designer simulations invariably show a single hump.

What about the pi-L? Eq 28 finds an "image" resistance. We then use an equation just like Eq 17 to calculate a pi network from plate to image, then an L network from image to 50 ohms. For a chosen image resistance the L and C values are again unique and there is one response peak.

If I do all of these things and if the output load is a resistance of the right value (50 ohms) the transfer function equation, as plotted with Mathcad or Radio Designer, I do not show double humps. It is possible that if the output load contains reactance of some kind a double-tuned circuit would result that might behave like two coupled resonators.

The pi and pi-L are basically single-tuned circuits, not coupled resonator circuits. The two capacitors do nothing more than transform resistance from plate resistance to a 50 ohm load resistance. The coupled resonator circuit requires two pairs of complex conjugate poles and the pi and pi-L do not normally have these.

I have ben a ham for a few short years. I have been HF mobile for most of the time.

I have NEVER had my tri-mag mount grounded to my luggage rack until yesterday.

Another operator noticed noise on my transmission that was NOT caused by

the lack of this ground wire but it started him asking questions. He suggested that my antenna (ham stick) would work much better on 40 and 75 if I had this wire from my mag mount to my car body.

I never dreamed it would get rid of that S5 or S6 fuel pump noise that I

have put up with for over two years now! A small 12" wire and 90 seconds

of work.

It is completely gone! As is most of my electrical noise.

My question.....
Why did it get rid of the electrical noise?

Any boy want to help Elmer this Extra class ham. I would be thankful.

Paul - K4KJ

Source record: 175074

Hi all
Why are so many new hams so reluctant to use ladder line for feed line?I'm a relatively new ham and I don't have a problem using balanced feed line, and don't understand why others are so resistant to use it.I have a 160 meter horizontal loop fed with 300 ohm twin lead that gives good results and no TVI problem or any other trouble other than some effect when it's wet.I plan to try ladder line to help with the weather effect.
I also have a parrallel dipole for 80 thru 10 meters that is fed with RG-8.It gives very good results.It seems that many are reluctant to try these antennaas as well.Am I missing something here?I'm pleased with both of my antennas.No they do not give beam performance, I speaking of wire antennas only.Antennas of these types , to me, give very good performance for having one antenna and one feed line to cover multiple bands.I know a few other hams that would like to have one feed line/antenna to cover several bands, but they do not like ladder line, and have no experience with it! Also they seem suspect of the parrallel dipole.Why?I feel that I may be looking at things wrong in liking these types of antennas.
Also is it possible to feed a parrallel dipole with ladder line?I know it seems pointless to feed a 60 or 70 ohm feedpoint with balanced line, but I'm just wondering what the results would be.
Thanks for reading, and thanks for any info to help me see what it is I'm missing on this subject of balanced line and wire antennas.

<snip>

Because all the radios built in the last 50 years or so have coax connectors
on the back of them.

Because you can do things with coax you can't with ladder line, like tape
it tightly to a metal mast and bury it.

Because the only ladder line you can buy at Radio Shack is 300 Ohm TV stuff.

Sure there are sometimes technical reasons why ladder line would be the
"better" choice, but most of the time coax is the path of least
resistance (pun intended).

Without the 12" ground wire, the ground for the antenna is made back through the coax to your transceiver. This makes the braid of the coax part of the antenna and therefore places part of the antenna inside the car where it is much closer to the car's wiring and the associated noise. Glad you got it fixed.

Ok, here are two reasons:

1. All commercial transceivers are designed to feed 50 ohm coax directly.
Using non-50 ohm balanced line requires something additional - either a balun or
tuner. IOW, coax is plug-and-play.

2. Coax is not as critical as to installation. It can be run through metal
conduit or laid next to a metal gutter or other metal object, or even buried.
Balanced line can not, unless you're talking about shielded balanced line, which
I don't think you are.

The only advantages I can see for balanced line are slightly lower cost and
slightly lower loss. For most hams, those are not sufficient reasons to
outweigh the advantages of coax.

Hi Rob!

Can't speak for the new hams, but I've seen the
same reluctance in the older hams as well. (By older
we really mean more experienced...HI!)

Personally, I have been experimenting with wire antennas
for some time, and currently use an 80 meter doublet
fed with 450 ohm ladder line. It works great, and I
usually get asked the question: Why ladder line?

Well... Because with the ladder line and tuner I can
use most any wire to get a signal out with the least
amount of struggles. It's that simple.

I have tried many designs for wire antennas, and in fact,
my favorite is the loop. I plan to try an 80 meter loop
as my next antenna. Sometimes the direct coax feed
is usable, sometimes not.

It all boils down to what works for you and fits the budget.

Hope you have better luck with Force 12 customer support than I have. I bought a Force 12 C-4 in 1996. It's a good antenna, and I like it. But I have NEVER been able to get ANY support from Force 12. When I got the antenna a couple of the elements appeared to be the wrong length. While it was pretty obvious that they needed to be cut, I wanted to double check with Force 12 before cutting them. I called, and was told by the secretary or receptionist that they were "really busy" and I should call back later. Later calls went unreturned. I sent a FAX. It went unanswered. I finally cut the tubing to the correct length and the antenna went together and worked fine. As I said, it's a good antenna.

About a year later I was up the tower doing some work on another antenna when I noticed that the U-bolts holding the 10 and 15m elements on the Force 12 were rusted. The other U-bolts were fine, so I called Force 12 to ask about it. Nobody returned my call. I emailed them. No reply. Finally (after a Usenet post asking if anyone else had experienced any problems) I got a reply from their east coast rep, and he promised to get an answer for me. I never heard anything else. According to the rep, Force 12 was going to send some replacement U-bolts. I never got them, and never heard anything. One more email went unanswered.

They may produce good antennas, but for me, customer support has not just been poor, it has been non-existant. And I was always cordial in my emails and FAX correspondence with them, never demanding or rude.

I know it can be a difficult market - I spent a number of years designing and producing amateur radio products. Margins are typically low, customers won't read the manual, stuff gets hooked up incorrectly, etc. But there is no excuse when a company ignores a customer's phone calls, emails, and FAXes.

Roger,

My point was that in a later post he indicated that he was going to be
using legal communications frequencies, thereby invalidating the harse
reactions he received. He shouldn't have had to do this in order to

get a cordial response. The fact that he was referring to legal communication methods emphasizes that he should not have been pre-judged by this community just because he said that he wanted to communicate with an aircraft. If he had said that he wanted to communicate with the Space Shuttle or the International Space Station, would you all have assumed that he was going to pirate NASA TDRS frequencies? And what if that had indeed been his intent? It's arrogant and self-righteous to (pre)judge intent - people should be (and ultimately are) responsible for their own actions. I think people are taking the "self-policing" aspect of ham radio too far here. To me and many others, "self-policing" means one regulates their OWN behavior - it's not a license to indict or criticize others through vigilante-style action - "OO" activities notwithstanding.

To gauge your own position on this, consider the following scenarios:

1) A CB enthusiast asks about how to modify a Henry 3K for 11m.

2) A person interested in pirate FM operations asks about how to redesign a solid-state RF power amp for 3m operation.

What would you do in these cases? Would you:

a) Provide purely technical information without judgemental overtones?
b) Advise them about potential legal problems, but offer technical advice anyway?
c) Refer them to alt.radio.pirate or a CB newsgroup with no technical help?
d) Respond in a condescending legalistic manner, refuse to provide any information, and be filled with righteous indignation?

Which of these responses best characterizes your probably reaction?

Which response puts the best face on ham radio?

Curt Breneman

I think I explained that in the next sentence, with further elaboration in the rest of the post. The method I eluded to is the standard one for determining the performance of MW antennas. There is a body of knowledge and data about MW vertical antennas that extends back at least 75 years. It is in light of this knowledge that the data would be interpreted.

Most of the CFA naysayers will be astonished if it performs within 10 db of a 1/4 lambda vertical monopole over a good ground system, for which there is an enormous amount of measured data.

If the CFA does perform anywhere near as well as a 1/4 lambda vertical monopole, then it might be worthwhile characterizing its performance in greater detail. It isn't necessary to determine whether the emperor is wearing Armani or Brooks Brothers if it is first determined he isn't wearing any clothes at all. (c:

If the CFA doesn't appear to perform any better than any other short fat antenna, it might be useful to some to determine just how much better or worse this is. But this data isn't likely to be of much use in the broadcast industry where most of the current action in the CFA world is.

It will probably be up to hams to get some kind of handle on how the CFA performs at HF, though it is possible the military might get interested. As I eluded to before, meaningful measurements at HF are very hard, if not impossible, to make.

If what we are interested in is determining whether the CFA proponents have indeed managed to reinterpret Maxwell's equations in a new and valid way, then what I would like to see are measurements made at UHF. It is actually possible to make antenna measurements at 450 MHz that are meaningful and reasonably accurate.

Ah, now we have a horse of a different cruller. Where before we were talking about ground stations, now we are talking about airborne stations.

In short...for relatively minor installations (a simple navcom or for that matter a whole "stack" of avionics) that don't require complex (as the *INSTALLER* defines complex) operations, any certificated airframe mechanic (i.e. the "A" of A&P mechanic) can install and sign off the installation.

For major installations, there is a special form (337) that the installing airframe mechanic must fill out, and then a representative of the FAA with an Inspection Authorization on his/her A&P certificate must approve the installation and return the aircraft to service.

Another way of doing the same thing is for a SHOP to have a certificate and one or more of the shop technicians qualify for a REPAIRMAN certificate that allows them the same privileges as the airframe mechanic, but for one particular class of equipment, in this case radios.

Nowhere is it stated that the mechanic or repairman must be the one that does the actual nuts and bolts of the installation. I can hire a high school kid to do the installation, or for that matter the major installation if I'm willing to put my A (or IA) on the line for the inspection of the work.

Good point. 100' of #6, located outside the house, connecting the
antenna and cable grouding block (male/male thingy) to my original
grounding rod will alleviate both the dual-rod issues as well
as your concern regarding 'keeping the lightning outside the house'.

Thanks again.

Hi Dave,

You want to break the curve up into straight line intervals. For some curves, two or three are enough, for others - more. This cannot be answered any more simply than to keep increasing the number until the results stop changing significantly. What constitutes an insignificant change? Good luck - that's what makes debate in the newsgroups. :->

I like your slotted line project. Another variant is known as a slab line. This is a center conductor between two parallel plates. With such a design, the center wire is oval in cross section. (Proceedings of the IRE, Vol. 38, No.3(Mar.'50)p. 244).

Beware that any probe that over couples will introduce SWR and create false readings across the board. In the lab with milliwatt sources, this cramped our style. At HF with 10's (if not 100) watts available, the coupling of -20 to -30 dB is no great regret.

Following construction you should measure its SWR and insertion loss driven in both directions against a very good 50 Ohm Load.

All of the reasons mentioned, plus I think it looks like crap and it tends to be not very rugged. Also it's sometimes nice NOT to need a tuner if the antenna is built.

KG4GGX,
Another two-cents worth...
People seem to have a phobia about using a tuner, something
to do with being afraid of the losses in the tuner, I guess.
Sure, there will be some loss, but compaired to the 'agility'
you have with a tuner and ladder-line, the losses don't really
amount to much.
I think the 'wive's tales' about ladder-line causing RFI
have a lot to do with it also.

Where is the cable grounding block? You want the wire from the mast to go to ground in a straight line with no sharp bends. So preferably the wire from the mast would go straight down to ground from the mast. If you go to the first rod, I don't see how you will be able to do this unless this rod is below the mast also. Lightning doesn't really make turns well. MK

Yes indeed. You DO need a good body ground for the magmount if you are using it at HF. At VHF -- though perhaps not at 6 meters -- the capacitance of the mag-mount to the body metal may be enough to act as an RF ground. But at HF, the return current does not flow back through the body, but comes in on the shield of your coax. I have been able to operate on 80 meters with a home-brew magmount -- but I didn'' try to make that work as a ground; I bolted it to the car's body with a short strap. Current has to go somewhere, and I'd rather have it go where it SHOULD go.

I think I need to re-clarify.

I have a metal mast connected to a wooden chimney. On this metal mast
I've installed a cable grounding block (male/male, RG-6 connector with a
screw/screw-hole to enable attachment of #10 wire (might be limited to #10,
I need to check if larger wire is possible) In any event, I've ran a #10
wire to an new grounding rod. This new rod is located directly below the mast.

I gather from your previous post, I should utilize my new rod since it
is optimally located. (directly below the mast, low inductance path).
However, to alleviate the problems inherent with two distantly located
grounding rods, I should also connect these two rods with #6 wire.

Am I still confused? :-)

TIA

You have to be more careful with ladder line than with coax. Its RF field is not contained inside a neat and easily routed shield, sp you should keep it away from other conductors. The National Electrical Code requires a LARGE spacing to power, telephone and other wiring - I think it may be 12 inches -- and standoffs for mounting. You can't meet the National Electrical Code grounding requirements without a real lighting protector (all you have to do with coax is ground its shield properly). It doesn't take well to being flexed, which can break it. Rigs don't connect directly to it, being made for coax.

Adding up all the installation problems -- if you did follow all the rules -- and making the antenna resonant (which is anyway a good idea) doesn't' seem all that much of a tradeoff.

That's how I ground my TV antenna mast. I use #8 aluminum to listed
clamps at the mast and at the water faucet. Atop the mast is my discone.

Regarding the antenna discharge unit, here's what the NEC says:
"810-20. Antenna Discharge Units ï¿½ Receiving Stations
(a) Where Required. Each conductor of a lead-in from an outdoor antenna
shall be provided with a listed antenna discharge unit.
Exception: Where the lead-in conductors are enclosed in a continuous metallic
shield that is either permanently and effectively grounded or is protected by
an antenna discharge unit.
(b) Location. Antenna discharge units shall be located outside the building or
inside the building between the point of entrance of the lead-in and the radio
set
or transformers, and as near as practicable to the entrance of the conductors
to
the building. The antenna discharge unit shall not be located near combustible
material or in a hazardous (classified) location as defined in Article 500.
(c) Grounding. The antenna discharge unit shall be grounded in accordance with
Section 810-21."

Per 820-20 (a) Exception - you are not required to use an antenna discharge
unit if you use coax and if it is properly (per NEC) grounded at the receiver.

That goes to the NEC requirements, and is not intended to say anything
about maximizing protection. The NEC is a **minimum** in terms of
what is required.

People talk about lightning - and we don't have a clue what in the hell
we are talking about. NO ONE can predict what a "lightning strike"
will do. People give "knee jerk" advice, which, for the most part, is correct,

but should nevertheless be dismissed, until you think the suituation through.

Lets put certain kinds of damage aside, and consider electrical damage.
(I'm setting aside damage such as lightning knocking over a tree which
falls on your house, starting a fire which burns down your house - that sort
of thing.) What we are talking about is voltage and current on your
antenna system (including supports, down lead, ground wires etc), either
from a direct strike or induced by a nearby strike.

You MUST go to the basics: E = IR. You MUST have a potential
difference to have a current flow to do any useful - or damaging - work.
If you can establish a system with no potential difference, you prevent
the current flow - and the resultant damage. So in all cases, you are
better off having your grounds bonded together, to minimize the
potential difference. The size of the bonding jumper goes directly
to the potential difference. The larger the jumper, the lower the resistance.
The lower the resistance, the lower the potential difference.
NEC has stipulated that the minimum is #6 copper (or equivalent)
to bond a grounding electrode for your antenna to the house grounding
electrode system. That jumper tends to minimize the potential difference
between electrodes. Remember, the smaller that potential difference,
the less possibility of damage.

The same thing applies to the size of the wire that connects the antenna
mast to ground. NEC specifies a minimum size. The wire will tend to keep
the voltage (potential difference = voltage) between the mast and ground
to a minimum - the bigger the wire, the lower the voltage.

The forgoing nets out to "bigger is better" in terms of grounding conductor
size. But it also nets out to "have a single grounding system". And you
get a single grounding system in one of two ways: do not add a grounding
electrode OR bond any added grounding electrode to the groundning
electrode system. Thus the NEC requires the latter OR allows connection
of the antenna support to the existing grounding electrode system.

If you want to maximize the effectiveness of your saftey grounding system,
by all means add electrodes, maintaining (at least) the minimum requirements.
But if you add an unbonded electrode versus connecting to the existing
system, you violate NEC and potentially increase the possibility of electrical
damage.

12' spacing would be advisable for ladder line with about 5" conductor
to conductor spacing, however, for the so called 450 Ohm window line
the spacing recommended need not be greater than 2ï¿½" as the conductor
to conductor spacing of that line is only 0.8"

Certainly this, or any quantitative measurements, would be enlightening, and would add a great deal to our knowledge of this antenna. However, one of the practical problems of electrically small antennas is that they invariably exhibit a large feedpoint reactance and low feedpoint resistance. (As far as I know, the CFA isn't an exception to this.) Consequently, the necessary matching system is often the dominant and unavoidable source of loss in any useful system involving a small antenna. I don't think it would be possible to accurately translate the loss of the network at 450 MHz to the loss you'd get at a much lower frequency. It looks to me like it would be necessary to independently determine the impedances of the two portions of the antenna while it's operating, a problem like determining the operating impedances of each element of a phased array while operating. With that information, you could calculate or measure the expected losses you'd get in a phasing/matching network at other frequencies. Is this kind of independent measurement of the operating feedpoint impedances of the two sections possible with reasonable accuracy at 450 MHz, considering the values of the impedances involved?

Thank you for the comprehensive explaination. I realize this took
some time on your part and it is appreciated.

From your feedback, as well as other posts, I have decided to use
#6 copper to:

1) Connect my antenna mast to a grounding rod which I located directly below
the mast. This allows the least resistive/inductive path for lightning.

2) Connect this grounding rod to the 'original' service grounding rod.

Thanks,

3810. Skip LP versus regular LP ?

>73, Ed - N5NUG

That's right Ed!

Here is an antenna that is purported to eliminate all losses by use of something that simply can not happen, through some kind of "magic".

Even though the ground near the antenna is regular old bare dirt, they would have us all believe like morons that the losses in the dirt go to zero because of the feed system!

To top it all off, they want us to believe the power factor of a short elemebnt can be corrected with a loading inductor the same size used in a mobile antenna, or a capacitor like used in a small loop....yet unlike the mobile antenna the CFA's reactance canceling is lossless using standard components!

Since the loss in any small antenna results from exposure of the lossy media around the antenna to concentrated fields and from loading system losses, and since the CFA does nothing to eliminate the only losses that are a problem....only someone without a basic understanding of antennas would swallow the story they tell.

I suspect that's why, after around ten years or more of having the antenna available, it has degenerated to something talked about in amateur publications that are the equal of the National Enquirer of antennas.

I have two 40 meter Delta loops in the vertical, fed at the top of a 60 foot mast, than I would like to experiment with by feeding them all possible configurations, such as an 80meter dipole (bow tie type) as one LONG wire, and in and out of phase as two deltas....best I can figure it will take a switcher that is 4by 6 to two out...is there such a thing made...that is electrically operated, that I can do from the mast top, OR what if I feed them both with coax (instead of the ladder line Im using now) and do the switching with a plug in matrix at ground level (would be cheaper but may change the success of the deltas as they are now...anybody got some ideas? thanks 73 Murray K5MDM

3817. Re: Balloon Supported 160M Vertical Wire

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-10 00:52:26 UTC
From: Alan Biocca <Alan.Biocca@usa.net>
Message-ID: <etAY5.5890$M5.342859@news1.frmt1.sfba.home.com>
Source record: 175116

We have floated a Helium Balloon-Supported moderately long vertical the last two Field Days. The antenna performed well, while it lasted.

The first year it worked until the Balloon failed from stress. The second year we put a parachute over the balloon to alleviate the stress problem, but we put it up in the daytime saturday and the afternoon winds drove it into the trees to destruction.

It only works in very calm winds.

Also, watch for the static generated. It will give a good shock and can damage solid state equipment if not properly protected. We observed voltages sufficient to jump a half centimeter or so, and it appeared that if you waited long enough it would go considerably further.

Source record: 175118

Bill:

Thanks for that explanation of the PI - L.

[The extra capacitor together with its' mate constitute a simple impedance transformer and not additional dynamic elements in the network.] In this case, as you point out there will only be one "hump".

That's why I qualified my statements up the thread with "number of 'independent' L and C elements".

There are configurations/combinations of multiple capacitors [Known to filter designers as "Norton Transformations".] in which the pair or triple of C's are not "independent dynamic elements" but act together as a single element coupled to an ideal impedance transformer [Norton transformer]. The inductive analogy to this "capacitive Norton Transformation" is the tapped coil in which a single inductive element [L] contributes to the "dynamics" of the network and the tap on the coil acts as an impedance transformer. Capacitors can't be "tapped" like a coil, however the same effect can be achieved by using a pair or triple of capacitors linked so that they form a single capacitive element in the "dynamics" of the network but also act to achieve an impedance transformation.

These are two techniques [tapped coils and capacitive Norton transformations] used by high order filter designers to achieve a practical circuit with a low ratio of element values in a high order filter. Often the calculated theoretical element values for a high order filter have a very wide ratio and make for an impractical circuit design. Then by a process of impedance transformations within the filter network using tapped coils and capacitive Norton transformations, the high order filter designer can often achieve a very practical circuit with a narrow range of element values.

Golden Gate Bridge...

What about skyscrapers?

The twin Petronas towers in Malayasia are the world's tallest buildings.

I thought that if one could place transmission lines in the right places, one could probably make a close spaced [W8JK style] superdirective 160m vertical beam out of those towers.

Might be worth a trip out to Malayasia for the next 160m contest.

Wow. Definitely both ends of the spectrum. I'm glad you received good
support - that's what I would have expected (and did expect) from
Force 12, given what I'd heard about them. And perhaps that's the norm
now. I hope so. But given my own experiences with Force 12 I'm not
likely to find out - I don't generally reward poor customer service
with repeat business.

The nice thing about the C-4 I own is that there's not much that can
go wrong with it that I can't easily fix, even without customer
support. And I do like the antenna.

Rick:

ec: Tom...

You were lucky enough to find one, eh?

Oh, yeah... youv'e obviously been using the North Pole magnetic pillows.

The South Pole magnetic pillows have the reverse effects.

And... the North Pole magnetic pillows are really scarce. As you well know, Maxwell's Equations [Integral form] show that the maximum likelihood ratio of finding North Pole to South Pole pillows is at least 10 million to one.

I found that if I placed the floating high gorky close to the low yo yo and then put the pillow cover over the South Pole then my headaches are reduced somewhat, but I noticed an interesting side effect of this pillow modification is that when the pillow is used during sex rather than sleep, Viagra effectiveness is enhanced 100 times.

Of course this only works if you are over 75 years of age. This should prove a boon to most hams.

Randy,

Stacking of antennas is not a trivial exercise. It is pretty much beyond the
scope of an Internet forum to educate you adequately on this subject.

You should acquire a good antenna book (e.g. ARRL Antenna Book) and do some
study. You can get some good answers to specific questions in these forums,
however, you can get an awful lot of misinformation too, as can be demonstrated
by some of the other answers to your query.

>
>Let me see if I understand if I "stack" 2 2MCP22 antennas each having 16db gain
>would that give me 32db gain??

Alas, it should be so. In theory, you can gain 3 dB by doubling the size of the
antenna ("stacking" two like antennas). In practice a better rule of thumb is
to figure on 2.5 dB.

Wes

Cry me a river. If you don't like what I post, don't read it, FOOL.

There are plenty of books via the ARRL on EME..in particular the ARRL
Antenna Book has a detailed chapter on that particular subject.

Many years ago we used an 8' helium baloon using a roll of wire from a
MIG (sp?) welder as both the support and the antenna. It went up over
three hundred feet. The next year we used a 12' helium baloon
figuring it would go much higher. It did. We had to stake the TS-830S
we were using with a tuner firmly to the ground as it picked the radio
off the table. Alan is right about the static shock. It will curl
your hair.

3830. Parallel Dipoles es Ladder line ???

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-10 03:53:17 UTC

HI
Thanks for all the replys.Still with all the reasons against ladder line, what about those that want one feed line and one antenna.Yes one can tune an antenna to resonance, but not one wire that works 80 thru 10 meters.Yes one can make a trapped antenna work multiband, but traps are lossy as well as tuners, and make a more complicated antenna.So if someone wanted a simple home brew wire antenna to cover 80 thru 10 meters, ???It seems to me a balanced feed line antenna system will do this fairly well.I don't think a coax fed single wire antenna without traps will do this kind of multiband coverage very well.It would still require a tuner and have much more loss, if it will load up on all bands.
Then if coax was desired for such an antenna for the reasons stated before, what's wrong with a parallel dipole?Once tuned it can cover many bands with out a tuner and a coax feed direct to the rig.Why are they not liked?I have suggested both the balanced feed line antennas and the parallel diploe antennas to some of my ham friends.They seem to not want anything to do with ladder line or the parallel dipole, and have no experience with either.I am currently using both with good results and no problems.What is wrong with a parallel dipole to operate several bands on one feed line and no tunning needed?I know of at least three hams that want as many bands of coverage as they can get , but only have room for one antenna.I'm vey puzzeled.Is there something wrong with the parallel dipole??That would be a good choice if one could not use ladder line it seems to me.They all seem interested in the G5RV.It uses coax and a balun and a tuned ladder line feeder.
Anyway, for my own info, is there something wrong with a parallel dipole??I assembled , and tuned the one I'm using on my own and I'm a new ham.I have been pleased with it for the multi band coverage and no retunning between bands.I have also worked a fair amount of dx with it with good luck in pileups, and good RST's.It's only up 30 feet at the feed point,and flat topped. Also my 160 loop fed with twin lead to a 4 to 1 balun, up 45 feet does reasonably well tuned by the built in ATU in my FT-920 on 160 thru 6 meters.Better on some bands than others, but for one antenna and one feed line they both do well.What am I missing??
Thanks for reading, and thanks for all the replys.

Dino,
LB CEBIK on his website has two articles on the T2FD design and basically confirms your experience(s) (http://www.cebik.com/radio.html). Although there is a power loss say of 75% or more on 160m do you think that the problem on 160m could be it is a cloud burner at that height and good for mostly local contacts (300-500 miles). And unless the conditions are right for a vertical bounce on 160m there may not be much performance? Reason I bring that up is I have run a 66 ft endfed wire at 10 ft and worked out 800+ miles SSB on 1-2 watts using a QRP+ rig but only when conditions are right. I am sure the Effective Radiated Power is very very low for this arrangement. If you check out http://www.spacew.com/www/fof2.html it will give you Near-Real-Time F2-Layer Critical Frequency Map for checking this out. I am not saying that the BWD is an efficient antenna on 160m but can be effective when used within its constraints. If you look at most 160m antennas recommended they typically are capacity hat type verticals anyways not horizontal dipoles. These shortended 160m verticals generally fall in teh 25% or less for efficiency from my readings. (Just my $00.02--smile)

I know about the Norton transformation, applicable to bandpass filters, and have used it often. One example is a five pole half octave Chebyshev bandpass filter in chapter 17 of "HF Radio Systems and Circuits" by Sabin and Schoenike (ARRL item #7253). The idea is to get five equal inductor values. The disk attached to the book has the software for it, written in Visual Basic.

As you say, the extra capacitors transform impedances but do not introduce additional poles.

Tom,

Thanks for your response concerning the CFA. I did loop up the CFA thru a search engine called Dogpile. It pulled up all sorts of paranormal psychic hype along with the antenna URL that I posted.

I guess a lot of the vernacular used to describe psychic events was also contained in the description of the CFA as catalogued by Dogpile.

Actually I believe that there are too many new hams that are not reluctant enough about using balanced transmission lines. While they certainly have their place, balanced lines have application problems that many newcomers tend to overlook.

> I also have a parrallel dipole for 80 thru 10 meters that is fed with RG-8.It

I use a combination of trapped and single band dipoles fed with a common balun/coax feeder. Interaction between the individual dipoles can be considerable so I operate them in a "crossing" arrangement, rather than having them all parallel.

I have a C4XL. I have been happy with it and I got good telephone
support for both technical questions and replacement parts.
The rusty u-bolts are a fairly well known issue. Force 12 believes
that stainless steel is a poor choice for the u-bolts because it is
subject to galling. This can make it extremely hard to remove the
nuts later. They ship stainless hardware with their antennas
except for the u-bolts, I found. If you read very carefully in the
manual (at least my manual), they clearly state that they recommend
the non-stainless u-bolts be spray painted. I put multiple coats on
mine. It definitely slowed down the appearance of rust, but in time
it does show up. It should be pointed out that this is *not* a major
problem, IMHO. It is at worst unsightly. When the time comes to
remove the nuts from the rusty u-bolts, they are going to come off
pretty easily. The same can not be said for badly galled stainless
hardware. Personally, I buy Force 12's argument about the u-bolts.
There are a lot of stainless u-bolts used out there, however.
Others may disagree. 73, David K3KY

Bill:

Yes... Norton transformers, I thought they were all but forgotten. Heh, heh.

With the advent of modern digital technology, digital filters, etc... these subtle and ingenious circuit design techniques will probably disappear as the older generation of circuit theory practicioners vanishes into that great circuit design laboratory in the sky.

There is nothing more beautiful than a practical, feasible, well designed LC passive filter network.

Art and Science blended perfectly.

Sigh...

very good advise wes
he will also need a good mast mounted preamp and also understand that EME is ONLY CW
not voice
its not like working any of the satelites which most of them are easy and using
voice
i hope randy does a bit more reseach before he starts spending large amounts of
money on antennas

I think that you are right that it would be nigh impossible to
independently measure the operating impedance of the two elements(?) of
the antenna at 450 MHz. However, absent any information as to the
coupling system or how it is designed, I have no idea whether being able
to do this is important or not.

On some level it doesn't matter, because, if measurements show the CFA
(feed system, matching network, warts and all) has significantly more
gain than a short fat monopole over a good ground (and equivalent or
better bandwidth), then the CFA folks are really on to something big,
whatever it is. At that point I don't think there will be any shortage
of folks who are spectacularly brighter than I, who will be devising
measurements and postulating theories for the rest to knock down.

For the time being, I am content to bide my time awaiting the results of
the H&D/dTL&R joint venture measurements. I'll reserve any speculation
on future tests till after the current tests are public.

I own a Force 12 C4 from about 14 months. Apart that is is a very good antenna, I admit that stainless steel u-bolt give galling problems. Immediately after assembling the 10m elements with steel u-bolts (that I obtained upon my request from Force12) on the boom I have found that one of them had galling.
I think that if I need to remove this element in the future I will need an electric saw -hi!
About the customer service, I have found a lot of infos and help from Nathan W6XR of Force 12.
My experience is that they give first class service, concernig lot of infos and spare parts (sending me stainless steel hadware - special boom to mast assembly plate in a week from my order by air-mailfrom USA to ITALIA).
Concernig tha crazy things happened to the chap that bought the top-end Mosley antenna, losing dollars and antenna, I am sure I will not buy any Mosley product in next 50 yrs (I am 41) - of course.
I am sure that I will buy other Force 12 products - I am thinking about C19XR or C31XR in next future!

I agree with that. I tried to steer him to other sources the other day. There is no way anyone can totally design his system without being there. Or I won't anyway.. And what is safe for me, may not be safe for him. I don't leave my antennas, or grounds connected during storms. So the issue of potential doesn't mean near as much to me as it would him if he leaves his stuff hooked up all the time, and using ground leads coming into the shack. When I'm in the storm mode, my mast is a lighting rod. Nothing else. I have no leads coming into the house. They are all grounded together at the bulkhead outside. So in my case, if I get hit, it's pretty much like it hitting a tree in the backyard except the mast has a low resistance connection. It stays isolated from the house. And the only reason I haven't bonded my power ground to the mast ground is it's been set up that way since 1959 and we haven't had any power line conducted lighting damage in the 30 years we've had the house. And plenty of near hits on the power poles etc. So I decided to leave well enough alone in that dept. I have a pretty good clue what happens when my mast gets hit, but that doesn't help me much at all with his setup. Also to my way of thinking the NEC is not totally flawless. Take for instance this one:

> Per 820-20 (a) Exception - you are not required to use an antenna discharge
> unit if you use coax and if it is properly (per NEC) grounded at the receiver.

I think that ones kinda risky. Sure the coax will arc together at that kind of voltage, but I still wouldn't want it hooked to my rig. Also just because all the grounds in a house are bonded together doesn't always mean they will be at the same exact potential. With the rats nest of wiring in this house"attic" etc, thats one reason I didn't worry about that too much. Unless all the leads are hooked to the central mast ground in a star pattern, it's my thought that they still won't be totally at the same potential as far as the lighting is concerned. Kinda like using a bus in the shack. The ARRL, and maybe even the NEC say this is good practice, but most in the lighting biz prefer a star hookup to a central bulkhead. So my plan was to isolate the "lighting rod". Works for me, but he can't do that in his case.But anyway, just shows there is alot to digest to all the protection, and I sure wouldn't just listen to

any one person. especially me. I'm sure no lightning pro, but I do live in a heavy lighting zone about 8 months out of the year, and have had many near strikes. The last one a direct hit on my mast a couple of years ago." with me at this puter 15 ft away" I've never had any damage yet,"in about a 25 yr span here" so I must be doing something right. But I only do my own dishes in that dept. Thats why I only give kneejerk lightning info on the net. g They are the ones that have to decide what they really need. They are the ones that will have to sleep with what they've done. Or satisfy insurance, etc, MK

I know that Gray is a true believer, but certain parts of this post need comment. Note that my comments do NOT have technical content, but concern the blind belief, only. Comments are inside the original.

Gray Frierson Haertig wrote:

> I think that you are right that it would be nigh impossible to

It's not important. Why go to scaling when there are claimed to be full sized units operating. Offers to measure these have been refused, according to much that I have read.

>
> On some level it doesn't matter, because, if measurements show the CFA

> gain than a short fat monopole over a good ground (and equivalent or
> better bandwidth), then the CFA folks are really on to something big,
> whatever it is.

Gain over a 'Fat monopole over good ground' is not the claim. The claim is that the CFA can replace a conventional vertical with comparable results in a smaller envelope.This claim has never been demonstrated by an independant measurement, at least that I have seen reported.

At that point I don't think there will be any shortage
> of folks who are spectacularly brighter than I, who will be devising
> measurements and postulating theories for the rest to knock down.

>
> Gray
>
>
I remain willing to accept this if reports from reputable experts substantiate even a part of the claims. There are units that are claimed to be operational, but have not been evaluated in believable ways. It seems SO simple to me. Why has it not been done?

I think for the most part new hams are best off with coax. At first
anyway. It's hard to screw up a coax fed dipole or GP or whatever. On
the other hand, it's easy for a newcomer to improperly tune a tuner. And
the poor guy will end up with half the signal he would have with coax
feed. After they get a good grip on things, then try the ladder line and
tuner. I'm sure this will start a flamefest...Suit donned...

Yep, thats the way I do it. The farther apart the better. You can get a
close spaced set tuned, but why go thru the aggravation. It can be a
real pain unless you are used to them. Also an advantage to 90 degree
spacing is you can lose a leg, and it won't effect the other bands much.
Almost no interaction at all. I have 160,80,40 on one feed. I get a
little interaction on my 40 legs, but nothing to get in a twist over.
And it's actually a guywire problem rather than the other legs. MK

That is nice, but I always thought the most beautiful thing in radio was the
crossed ellipses of a perfectly tuned RTTY signal, especially when it's a new
country coming back to your CQ.

The basic problem is the worship of 50 ohm feedpoints. Some huge number of hams much prefer putting up lame g5rv's and such for no other reasons than you can get one ready to go for a few bucks, convenience of installation, autotuners, etc., plug 'n play mindsets. Never mind the losses and limitations. Versus putting up an efficient dipole of any length fed with open wire line which can be to tuned to any HF operating freq. But which requires knowing how to tune the thing. Perish that hideous concept.

Hi Bill
Thanks for the reply.Suppose you want one simple inexpensive antenna with one feed line freely suspended in the clear to operate 80 thru 10 meters?I use such antennas with no problems.I have been asked by a few freinds for suggestions for an antenna that will fit these requirements.They both have big rigs with built in tuners, and manual tuners.They seem to think you can just put up some wire and run coax from the tuner to the wire and work all bands with a big signal.I may be wrong, but I don't think this will do all that.They like G5RV's, but, don't they use ladder line and a balun and require a tuner?I also recommended a parallel dipole.I built one without too much difficulty, and it is coax fed and doesn't require a tuner.It is my main antenna at this time, and I have good results breaking pileups and get good RST's in general with only 100 watts out.But they turn their noses up at this antenna as well.Is there something wrong with these antennas?
Thanks for reading.

Hi John
Thanks for the reply.Can one simple home built antenna work 80 thru 10 meters without needing a tunner.I have and use a parallel dipole that does this.But those thgat I recommend it to don't want to try one, nor do they want to use ladder line.But they they have room for one antenna and only want one feed line.Yes I know G5RV.It uses 31 ft of ladder line a balun and requires a tuner.
??????????
Thanks for reading.

I have one, it works very well, and is just about as efficient
as an antenna can be. If one varies the length of the feedline,
one doesn't need a tuner. It's on my web page. Click on
"W6RCA's No-Tuner All-HF-Band Antenna"

Please note that the coax loss in dB is the same with or without
the tuner at the transmitter end. A tuner at the transmitter
doesn't change the SWR on the coax. Tuner losses are in addition
to coax losses.

Ladder line vs Coax folks:

Hear Cecil... when he says that the coax loss is in addition to the tuner loss...

that's why it's most efficient to use a tuner with ladder line, and less efficient to use a tuner with coax. Sometimes remarkably less efficient, depending upon how far you want to go with your "tuning". Heh, heh.

Real hams don't use coaxial cable, that's for CBers and Military installations, real hams use open wire feeders or ladder line!

Heh, heh, yes that's right someone might actually learn something about electromagnetics, and gain a deep understanding of the physical principles underlying radio communications to boot, if they used open wire feeders and learned how and why a tuner operates.

Perish the thought of that!

Just use your store bought cell phone if you don't want to learn about electromagnetics.

Real hams use open wire feeders and use tuners or some equivalent... why? Because it builds character...

All the posts about Force 12 are a good example of what I was trying to point out.

You can see exactly what the danger is in believing one person's experience. One person had a bad experience with Force 12, and others did not.

Now let's say that one person who did (real or not) have a bad experience spent hours upon hours going around badmouthing Force 12. You can easily see, if he had the mindset to be a problem, the people with good experineces would be drowned out.

That's the danger, and it is a very real danger, of believing one person's comments represent the overall experinece of many.

Now if a few dozen people were bitching and whining, it would be a different story. We could be sure there was a problem of at least some extent. I hope we all consider this before jumping to conclusions.

Bill:

MFJ... heh, heh.

Well, I'm not a stockholder, but Martin F. Jue is a friend of mine.

And... under a variety of trade names, he makes some damm fine tuners, not as good as my homemade ones, but good...

Sometime Bill, if you ever get a chance, trip on down to Starkville [Missippi State] MS, and visit with Martin at one of his many factories there.

Starkville is just across the AL-MS state line a few miles west of the UA [Crimson Tide] campus in Tuscaloosa, AL. Starkville is the home of Mississippi State University, which has a very neat Engineering school.

The two biggest industries in Starkville are: 1.) Missippi State University (MSU), and 2) Martin's small manufacturing empire consisting of -MFJ, Ameritron, Vectronics, Mirage, HyGain, etc...

If you call or write before your visit, Martin will make a big cheer on you, and you'll get some insight on what it takes to break even and make a little money and stay in business selling neat stuff to hams. Hams are notorious bargain hunters...

From: David <k4zzrNONSPAM@gate.net>
Message-ID: <910ivm$1260$1@news.gate.net>
Source record: 175017

Ok guys, I need some advice (please)....regarding my station grounds.

Here's my setup right now: The base of my tower is located directly outside my station (within three feet). I've got eight 8' ground rods extending out into the yard from the legs of the tower using #2 bare copper wire. I have a large copper bulkhead attached to the side of the house (also just outside the shack) where each coax cable and rotor cable attaches to I.C.E. lightning protection devices and then the cables run into the shack. The bulkhead (with big insulators on the wall) is about a foot above the ground. There's also a 2' piece of copper strap used to bond the tower base with the "single point" bulkhead. And, there are three additional rods connected to the bulkhead spreading out 12' in each direction underneath it. All of this is for a bit of lightning protection here in south Florida.

From the back of my desk all of my station equipment is attached to a 1 1/2" copper strap running directly outside to the same bulkhead for my "RF ground" connection.

Is this the correct way to attach my RF ground? Should I be running directly to that bulkhead or run it to a couple of independent ground rods? If I should be running it to separate ground rods, they would have to be located within a foot or less of the existing "lightning" rods because of the proximity of the tower. So the question is, do I leave the RF ground strap connected to the bulkhead or run it straight into the ground with a couple of rods not directly connected to the bulkhead? I want the best RF ground connection I can get.

Thanks,
David, K4ZZR

> according to much that I have read.

You may have missed my posts earlier in this thread, but independent
tests are currently underway (or will be shortly) of a test antenna in
GB. It is what you characterize as a "full size" antenna - that is, it
is designed for operation at MW.

As I said previously, if the desire is to determine whether the CFA
operates in some radically different way than conventional antennas (and
such is, I believe, the inventors' claim) then tests at 450 MHz might be
much easier to carry out and more definitive, both because of the size
of the test antennas and the possibility of constructing an antenna test
range that is actually reasonably accurate. Note that these tests would
be of "full sized" antennas designed for operation at 450 MHz.

One of the problems of testing antennas at lower frequencies is the
inability to create a volume on the test range in which the amplitude
and phase of the incident test signal are well characterized, that is
large enough to rotate the antenna in around all three axes. Antenna
tests below mid VHF are really tests of the antenna and the environment
together. At sufficiently low frequencies, mid MW and below, the
wavelength becomes long enough that most terrain features and most
things sitting on the earth are a small enough fraction of a wavelength
that they have little effect, however, ground parameters still have a

strong effect. In order to interpret the results one needs a
sufficiently large body of measured data on a variety of other antennas
and ground conditions to be able to make sense of the data collected for
a new antenna. Fortunately this exists for standard vertical monopoles.

At MW and lower frequencies it is virtually impossible to make
meaningful measurements of the elevation pattern of a vertical monopole.
The elevation pattern is particularly important in MW antenna design
because it determines the skywave performance of the antenna. Current
practice for conventional antennas is to calculate the elevation pattern
from the current distribution in the radiator. The current distribution
is either measured directly or determined theoretically using MOM
techniques or sinusoidal approximations. Because the CFA claims
radically different operation, it is not clear that the conventional
techniques for determining the elevation pattern are applicable.

Tests at HF are particularly troublesome because antenna performance is
acutely sensitive to ground parameters at these frequencies, and god and
man have conspired to make almost everything on earth just the right
size to have an appreciable effect on the antenna and on propagation.

> an independant measurement, at least that I have seen reported.

You are correct. As I said in a previous post, if the measurements of
the test antenna that are currently underway reveal that the CFA is not
anywhere near as efficient as a standard vertical monopole over a good
ground, then the next logical question is how it compares to a standard
short fat vertical monopole of similar dimension. While this may not be
of any interest to broadcasters, there quite well may be users out there
that could use a more efficient electrically short antenna - hams in
restricted locations, perhaps. If the CFA would offer them more options
for getting their signal out, then this is a good thing.

The SWRs were not "sky high", just too high for a fixed-tuned solid-state
transceiver. If they had been using SB-101s, they would have been in good
shape.

Source record: 174919

hello all:
I just came up with a new antenna. The CT Flyer(patent pending).
I was reading some posts the other day and saw one about a bowtie antenna for 10 meters to work the contest over the weekend. At the same time I just happened to glance over at the Christmas tree in the family room and darn if it didn't look a lot like half of a bowtie antenna. I figured if I could find a way to get it to load up and use the HO train tracks around the tree for a counterpoise I might just have something. Well, I can't divulge all the particulars but I got it to work on 10 meters and WOW what a signal it puts out. This is proprietary information so I can't spill it all on this forum but I did get into the contest with it and boy did I work a lot of stations. I can't quite figure out why the were all around the north pole and in that general direction. I'll have to do a little more research as it seems to be somewhat directional.
I just wanted to pass this on as I see it as a new breakthrough in antenna technology.
73's and Happy Holidays
Larry N0SA

PS: For some unknown reason the signal quality goes up if you have a red nosed reindeer close by.

No, the only "endorsement"for the A&P is the Inspection Authorization, which can only be added after a number of years doing maintenance after getting the A&P. (IA is the equivalent of the FAA doing the inspection, the IA signs on the behalf of the FAA.)

So far as I am concerned, there is no decent school in this country turning out avionics technicians. Most of them turn out A&P who were taught how to spell avionics, but that's about it.

> together.

This is all just smoke, because the real test that will be believable,
if not definitive, is a one- to one comparison with a standard antenna.
This will settle the points of claim, even if it does not give complete
data, as a test range would. For the same reason, tests at 450 mHz are
not the ones to use- there are more questions about the scaleability of

the matching networks that cannot be answered without coming back down
to the lower Frequencies, after all.

> At MW and lower frequencies it is virtually impossible to make
> meaningful measurements of the elevation pattern of a vertical monopole.

This is NOT needed to settle the claims

>
> Tests at HF are particularly troublesome because antenna performance is
> acutely sensitive to ground parameters at these frequencies, and god and

Hi Tom, I can agree with your thinking.
But I am sure that if the Mosley antenna saga was false, after the US ham has shooted so many time against Mosley on his web site, on towertalk and other antenna reflector, the Mosley firm sure would have taken law action against him and they also would have answered on ham reflectors to all these attacks.
It seem they dont reply so really this history seem true.

Be advised that your idea comes dangerously close to my "Thinking about, maybe, applying for a patient". While you purpose using a tree as the radiating element, I have used them for years as antenna support and just not got around to determining the re-radiation of the tree. My lawyers inform me that your train track is prior art, I.E.. Standard ladder line. It is at this point you tread upon my yet to be determined discoveries.

Please be advised that I have instructed my consul to do a Deja news search for any other occasions of you attempting to infringe on any Idea I have ever had. Please govern yourself accordingly.

Cordially

SWRs were in the 5-6:1 range with one of 'em, the other was simply kaput and they had no clue what was wrong with it. You're no doubt right, given a radio which actually had tuning knobs they might have been able to toss some RF beyond the trees. But then they'd have to know how to dip & load.

I am hard pressed to see how you can construe my posts as having blind belief in anything other than testing. But we don't always see our own posts as others see them. Just because I am willing to consider further measurements and investigation into the CFA doesn't mean I have any preconceived idea as to it performance. I think that you have read my unwillingness to jump on the vituperative bandwagon, trashing the CFA as snake oil, as some evidence that I am a "true believer" in the CFA.

I DO have faith in the team that is making the measurements at the test antenna in GB. I know the principle investigator personally and his reputation as a MW antenna engineer is international.

In reality, I am highly skeptical that the CFA will perform anywhere near as well as it's inventor's claim. I can't think of any antenna developments in the last 50 years, maybe 100, that have called into doubt any of the underlying electromagnetic physics. Certainly there have been many discoveries in technique in that time, but no substantial changes in electromagnetics. This is what makes me highly skeptical of the CFA.

As to whether it will perform as well or better than a short fat monopole over a good ground, I am considerably less skeptical about this possibility. Any improvement in electrically short antennas - even if only rather modest - will be welcome. But if this is the case, it would clearly be a matter of improved antenna technique rather than a shift in the underlying electromagnetics.

I have to disagree with you, Bill, this is not smoke, it is the reality of antenna performance assessment. Of course, range testing IS comparison to a standard antenna.

The CFA's inventor's primary application seems to be MW and LW broadcasting. As I said in a previous post, there is a sufficiently large body of MW data about the performance of 1/4 lambda vertical monopoles over ground systems that it is not really necessary at this point for the tests being made in GB to include measurements made with a standard radiator. If the CFA performs anywhere near as well as a standard radiator, there will be plenty of clamor to determine just how well, and I am sure side-by-side (as it were) tests would be undertaken.

The tests being done by the H&D/dTL&R joint venture should answer the question of the CFA's efficiency (actually, gain) at the horizon. However, before this antenna could be applied in the US the matter of determining its elevation pattern would have to be settled.

I don't think I implied that there should only be one set of tests and that they should be at 450 MHz. However, the results of the H&D/dTL&R tests are very likely to lead to the need for further testing, regardless of their outcome. If the CFA performs anywhere near as well as a 1/4 lambda monopole over a good ground system, then the question will be why, when theory predicts the opposite. It would indeed be a very exciting thing if the inventors did somehow manage to invent an antenna that required us to reassess the underlying electromagnetics. I am not holding my breath, however. However if, for argument's sake, the H&D/dTL&R measurements show the CFA to be a good radiator approaching the performance of a 1/4 lambda monopole over a good ground, then what direction should the research into understanding this phenomenon go?

On the other hand, if the results show that the CFA is just another short fat monopole, then that begs the question, just how good a short fat monopole is it?

If the results show that the CFA is nothing but an expensive dummy load, then the question to be answered is how did they manage to dupe all those folks in Egypt. Or maybe, some how the Egyptians have invented an

AM receiver that can suck the signal out of the transmitter! (c:

I agree that measurements at 450 MHz would introduce a different set of problems than measurements at lower frequencies, but it solves some other problems. Regardless of the efficiency question, measurements at 450 MHz might be very useful for determining the elevation pattern.

I understand this is all idle speculation, but on a Sunday afternoon when it is cold outside, I find idle speculation amusing and a bit of an intellectual exercise. That is good enough for me.

>
> > At MW and lower frequencies it is virtually impossible to make
> > meaningful measurements of the elevation pattern of a vertical monopole.
>
> This is NOT needed to settle the claims

It may not be necessary to settle the claims, but it IS necessary in order to apply the antenna.

I am not particularly interested in whether the inventor's claims are settled or not. I am interested in how the antenna performs and whether or not it might be a useful addition to my arsenal of techniques to solve my client's problems. I don't view the CFA's inventors as an evil that needs to be scourged; that once we've shown what charlatans they are, we can move on to other more important work.

It seems, at long last, they are doing what they should have done years ago and have invited an independent team of competent antenna engineers to assess the CFA's performance in situ. But I don't think that these measurements, regardless of the results, will spell and end to the interest in the CFA. I hope the CFA's proponents remain open and will provide information as to the design details of the antenna so that others can go on to do further research. Whether or not the CFA is the answer to a broadcaster's dilemma, doesn't mean that the CFA might not have application elsewhere, at other frequencies and in different situations.

On the other hand the CFA may well prove out to be as good an antenna as any other randomly shaped piece of metal of approximately the same size.

>

However, in practice, one-to-one tests with identical setups really aren't terribly useful at HF, especially in situations that most hams

are likely to encounter. It IS possible to infer some information about an antenna from tests like this, but whether it is possible to infer information that is useful in applying the antenna to a completely different environmental situation is very questionable.

The bad news (and the thing that is hardest for most people to accept) is that antenna measurements at HF are not terribly useful except in the broadest of senses. The good news is that it doesn't much matter. HF circuit performance is so dominated by local environmental conditions and propagation conditions that any subtlety in antenna design is mostly lost. While you will always improve your chances of a QSO by putting out the most power in the direction needed, the ether gods will always be the ones that determine whether that QSO happens or not. Just because a set of measurements taken under one set of conditions indicates a certain power radiated in a given direction, doesn't mean that Joe Ham will see that at his QTH. Most hams just don't have the bucks (or spouses) to control their environment to the extent necessary to assure reasonably similar performance.

Gary, get serious!

The guys hawking the CFA have been milking this out for ten years or
so now.

A reasonable person would conclude any honest vendor would:

1.) Test and document performance accurately on several antennas
BEFORE filing for a patent

2.) Test and document several antennas before selling them for big
bucks.

In addition, anyone selling antennas that had normal business sense
would:

1.) Test and document a few practical installations with independently
verified data by a well know consultant or engineerring firm

2.) Allow other to see the power being run, and measure the FS in a
working installation if they wish.

I find it unfathomable that for ten years we have heard constantly the
same excuse "we'll have a FS reading soon". Hey, if the thing was on
the up-and-up they'd have done that ten years ago, before trying to
take anyone's money.

>As I said previously, if the desire is to determine whether the CFA

>be of "full sized" antennas designed for operation at 450 MHz.

You onviously don't know anything about the antenna design, or the
claims, or you never would have made the statement above.

The antenna would be all but impossible to build accurately on 450
MHz, because of the scaling problems.

Not only that, the claim is the CFA eliminates ground losses (not only at the feedpoint, but in the area surrounding the antenna for a large distance). Since ground losses are impossible to scale at 450 MHz, the suggestion of a 450 MHz test is totally unreasonable.

This is all especially foolish, since they claim they have working antennas. Yet the antennas that work work only in countries that do not require serious documemntation of performance, and there is no documentation!

None of the above means anything in the context of this antenna and the claims made for the antenna.

>At MW and lower frequencies it is virtually impossible to make

That isn't true. All you need do is a simple A-B groundwave test. It is a vertical, close to ground.

>Tests at HF are particularly troublesome because antenna performance is
>acutely sensitive to ground parameters at these frequencies, and god and
>man have conspired to make almost everything on earth just the right
>size to have an appreciable effect on the antenna and on propagation.

It's easy as pie to prove the thing works. Since the theory is totally screwed up like a rubber watch, the reason there are no measurements is because they can't prove it works as claimed.

>You are correct. As I said in a previous post, if the measurements of
>the test antenna that are currently underway reveal that the CFA is not

>of any interest to broadcasters, there quite well may be users out there
>that could use a more efficient electrically short antenna - hams in
>restricted locations, perhaps. If the CFA would offer them more options
>for getting their signal out, then this is a good thing.

Ten years later, after taking or trying to take people's money, they
still haven't measured one. Anyone smell something foul in all of
this???

>I, too, await more data.

I suggest you be patient. It will probably take at least ten more
years to run through all the fools who swallow tall tales about
converting induction fields directly into radiation fields, and having
a type of radiation that does not induce currents in the earth below
the antenna....let alone having a lossless loading system for a small
antenna.

The false claims are so obvious, I'm amazed people waste their time
with this stuff.

Hi Ian,

The expense of fighting something like that is prohibitive, no matter
if the statements are false. Damages are often not recovered, even if
the claims are false.

In the USA, we almost have a right to say anything we want to say
without paying any penalty, it is not like other countries.

There has to be millions of dollars at stake to justify the expense of
a lawsuit, and you would have to have some hope of collecting the
money at the end.

Heck, 5 :1 SWR on 80 meters with 100 foot run of Rg-213 is only about
an additional signal loss of 1 dB... That shouldn't keep you off the
air.

Well, I challenge you to take back your claim that the SWR was
"sky high". :-) Remember, SWR can vary from 1 to infinity and
"5-6:1" is a lot closer to 1:1 than it is to infinity. :-)

: need to do. Comments (especially ones to make my thinking on this
: clearer) are most welcome.

: Cheers,
: Tom

Thanks Tom,

I took your advice and looked for a mechanical adjustment. While there isn't
an obvious one, I was able to loosen and reposition one of the gears in
the gear drive of the probes, and it now tracks the impedance within about
two percent. At the two ends of the range, the probe carriage is no longer
symmetric about the 50 ohm position like it was to begin with, so
my current theory is that one of the probes is somehow displaced
from the original position. However the mechanical adjustment seems to have
taken care of the problem, and the results now agree within a few percent
with my old General Radio 1601A and 1602B, and they all agree within the
same errors when measuring standards checked on modern equipment.

3893. ?? about B&W folded dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-11 00:36:40 UTC
From: Mike <w4mjr@home.com>
Message-ID: <3A34218F.9C6E404@home.com>
Source record: 174942

I came across one all tangled up. I am not interested in getting it back like it should be.My question is what ratio is the large balun on it and could this be of any use for making up another antenna. Also the large resistor in the center of the antenna can it be of use other than a dunny load.

Yeah, yeah, you *know* I didn't just get off the boat and land in
antennaburg, Cecil. Problem was that the barefoot radio shut itself down
when they tied the g5rv to it even though the SWR was low vs. feeding
the end of a half-wavelength wire.

Brian's point is that it keeps you off the air if all you have is a
fixed tuned solid-state transceiver, no tuner, a G5RV, and hope. :-)

Nuts! I screwed up.

Let me try it again. Here's the run down on the 5:1 SWR;

Band additional loss due to SWR of 5:1

80 0.45 dB

40 0.64 dB

20 0.9 dB

15 1.09 dB

10 1.25 dB

That sure doesn't look like a killer to me!

What's your point?, If you are comparing this ridiculous CFA situation to the Wrights, think again- heavier than air flight was known to be possible LONG before the event at Kitty Hawk. All the physics needed was known, and no new interpretation was applied.

Some years ago I made a MathCad program that calculated resonant
frequency and feed point from a geometric description of the patch.

I used it to design the 2m patch antenna (with the vertical stripe)
seen at

http://w3eax.umd.edu/spre/spre.html
http://w3eax.umd.edu/spre/tech_ref.html#antennas

E-mail me and I will dig up the program.

Doesn't seem that way to me.

In the first case - the quoted material from the ARRL text -
it is a checkpoint, similar to those found in many electronic kits.
It tells you what you should be capable of by a particular point
in the course, if you did the exercises. Many self-study courses
contain checkpoints. Some have tests at the end of each
section, which tell you to go back and review the section if you
got any questions wrong. And some have exercise "flows"
which allow you to skip some or all exercises. It is very
helpful to have checkpoints at the end of the sections that
tell you what you should have learned by doing the exercises.
(They should also tell you what you will learn by doing the exercises
at the beginning of the section.)

In the other case - what you posted - was intended to be, and was,
condescending, as you have stated. Context makes a big difference!

Any discussion of characterizing the CFA, at any scale, at any frequency, and to any degree of thoroughness is premature, if there has been no proof of ANY of the claims of the originators. Once some of the claims are proven to be even approximately true, then the number of people willing to help characterize it will be legion. Once a clear, independant statement of evidence is out there, you will have to beat the 'Me-too'ers off with a stick.

Nope, never attended MIT and never met Ernie, however... as you can probably surmise, I do have a couple of his textbooks and numerous of his papers in my collections.

My all time favorite, sits on my bookshelf not three feet from me, as I sit here typing this...

Synthesis of Passive Networks, Ernst A. Guillemin, John Wiley and Sons, New York, 1957, 741 pages, LC Call Number TK3226.G84, LC Cat Number 57-8886.

Guillemin, now there was an Engineer, they don't make em like that any more.

There are a few texts that go beyond Ernie's classic, but none approach his for style, lucidity, and elementary approach. A bunch of Ernie's graduate students also wrote some great textbooks after they left Ernie's tutiledge.

George, what era were you at MIT?

Happy Holidays,

Adam--

I've been using one for about 2 months with a Yaesu 847 & FC 20 tuner.

Its a fantastic antenna on 10, 15, 17, & 20. I've made contacts from Bangkok, Thailand to the Kingdom of Jordan and all over Europe and many more places. The other bands are probably just as good, I just don't use them.

> > unit if you use coax and if it is properly (per NEC) grounded at the receiver.
>
> I think that ones kinda risky.

Two points. First - Yes it is risky to your receiver if you do not disconnect the lead in. But that does not support the idea that the NEC is flawed. The NEC is a minimum. The fact is that it does not require you to disconnect. That would be an unenforceable provision, and would itself violate the purpose of the NEC (90-1 (a), which is practical safeguarding of people and property - NOT equipment - from possible dangers of using electricity. The requirement to disconnect, if it were in the NEC, would not be practical, as a matter of law. It is impossible for an electrical inspector to verify that all equipment is disconnected when a thunderstorm occurs. It would also violate 90-1 (b) which says that the code will contain provisionsconsidered necessary for safety. Disconnecting the coax from the receiver in the example you assume from what I wrote (ie the receiver is grounded and the coax is connected to it, thereby getting its ground) would violate 820 and 90-1 (b). (The flaw here is assuming that "at the receiver" means *via* the receiver.) Finally, it would violate 90-1 (c) which states that the code is not a design specification or an instruction manual for untrained people. It cannot instruct people to disconnect their coax when not in use without violating 90-1 (c)

Second - The NEC has the force of law, once it is adopted by the town, county, municipality - whichever governmental agency has jurisdiction. The exception goes to legality - it is not illegal to install coaxial lead in from your antenna without using a discharge unit. It also goes to the technical side: the coax will be at least as effective as the minimum size wire that the NEC specifies in conducting current to ground.

The key to this discussion is to treat the NEC as what it is: MINIMUM requirements for safety. If you do less than the minimum, you are exposed to possible danger - and you violate the law. If you do the minimum, you are less exposed to possible danger, and comply with the law. To illustrate, lets take your installation. A catastrophic short circuit occurs when a tree limb crashes through your wall and smashes your wiring so that a 110 volt cable contacts your "grounded" coax. Your coax will conduct current to "ground" via the bulkhead and thence to your antenna ground rod. How much potential difference will exist between

the coax and the house ground? Will the circuit breaker trip? The
answer is, you don't know. However, if the antenna ground rod is
bonded to the house grounding electrode system via a #6 bonding
jumper, the breaker will trip - whether the 110 volts got onto the shield
via the catastrophic tree limb caused failure or via a short circuit
within the equipment. And, by the way, there have been plenty of
cases where coax was "hot" with 60 Hz ac with respect to house
ground in television installations. If the receiver was properly grounded,
that could not happen. But if the receiver was not properly grounded as
mentiopned in 820, all the antenna discharge units in the world would do
nothing to provide the operator with safety. Those units will ignore 110 V ac.
So - your installation could possibly have superb lightning protection,
and NO protection against a short circuit that places 110 V ac
on your antenna lead in.

>better than a fullï¿½sized vertical radiator.

>Does this sound like a fantasy?

Sure does to me. If this magic radiator really worked as claimed, it
sure wouldn't be any big secret. Everyone and their sister would be
trying one on 160m. I haven't heard a single one tried yet. Maybe I need
to tune into the "magic" part of the band. I must be missing them all
with me constantly hanging out in the cw no mans land down at the
bottom. It's the last statement they make which really has me rolling.
An antenna 1/50 wl with no radial system is gonna outdo a 1/4 wl with
120 radials on MW. " I assume any self respecting BC would run 120
radials with a 1/4 whip"... Okeee dokeee...Maybe I should start
believing in the tooth fairy. MK

Source record: 174871

I read in this news group a while back on the best height for a six meter antenna, if I recall right someone was saying that one wavelength above ground,,,,, I think,,,,,,I understand it will work better the higher it is,,,,,,,,,,,,,,,,,,,,,,, but what I wanted to know ,,,,, what was the least elevation above ground that would work really well. Appreciate your refreshing my memory. thanks. Chuck Lorentson "73"

3917. "V" dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-11 06:06:53 UTC
From: rich a <rckchp@home.com>
Message-ID: <3A345FBF.F412C38D@home.com>
Source record: 174965

Greetings,

Does anyone have any info or advice about placing a dipole in a "V"
configuration, that is, with the ends higher than the center, the
reverse of an inverted "V". How would the radiation pattern be affected
compared to a "srraight" dipole? Better, worse or no real difference?
Thanks in advance.

Rich A.

Sure, but not in my case. I have no wiring that could be crashed down on my coax. Also my power electrical ground is still at a close ground potential with the rest. It's a dead short with any ohm meter from the box to any point in my ground system. It'll blow the breaker if that happened in my case. But again that proves my point, there is no way anyone can really judge what the other person is dealing with unless they see it all. And nowhere have I suggested anyone should ignore NEC specs. I've only stated what I do, and my reasons behind it. It works here, but I'm not suggesting he should do the same. With his setup, quite the opposite. In my first posts I had no concerns about his rig, I just wanted to steer him away from burning his house down. And thats mainly the concern of the NEC, so obviously he would want to look into that. Where I think the NEC falls short is the protection of a radio that is left hooked up in such a case. But, I don't do this, so I don't have to worry about it. I don't feel comfortable in a room with a connection to lightning, gas tube protected or not. At this point I still don't even know if he plans to stay hooked up or not during storms. That would have a big bearing on what he needs to do. If he's considering arrestors, I'll assume he will be, and he would sure want all at the same potential in the shack. Every single wire leading in would need to be suppressed to a common bulkhead to be really safe. But again in my case, I don't have to worry about any of that. I'm totally unhooked from the outside world. The only way I could further improve my setup is to add power line protection to the breaker boxes, but I'm too cheap. Also I really don't think I need them. Or at least with the past track record, I'm willing to take the risk of a big power line hit. That would nail me ham shack or not. But it's never happened yet in many years. The worst hit I've had power line led was a hit to a streetlight pole across the street. I got a spike, but was only enough to blow the fuse in my drake r4. Turned it black. But replaced fuse, and was back at it. No damage at all. Thats only happened once and was over ten years ago. So seems unless the hit was ultra close, most of the nasty stuff is damped down by the time it gets here. The pole strike was pretty close. Myself, I find lightning fascinating stuff. And it scares the crap out of me, when it's popping left and right around here, so I sure don't want to make mistakes. When it actually hits you direct , it's really pretty quiet, and ultra quick. Sounds like a lightbulb being thrown on the ground, with the overhead boom a split second later. Also the connection of the strike leader to streamer is above the mast about 150

ft or so I think. So the nasty bright stuff is overhead a bit assuming the mast is acting as a lightning rod. MK

A friend of mine calls that a perverted vee. Yep, they work ok. But I'd
prefer to get the center higher than the ends. The pattern about the
same basically, but I'd assume more ground losses with the max current
portions lower to the ground. Also I prefer a flat top over an inv vee
most of the time. Less ground losses if it's low, and more in the clear.

<SNIP>

I don't intend to require the removal of coax during storms. This
would mean I would have to connect/disconnect the scanner every time
I use it. I know this requirement would fall to human errer and lazyness.

FTR, I intend to ground my antenna mast via a #6 copper from the mast
coax/coax grounding block to a rod located directly beneath it. I also
intend to connect the two grounding rods (new/old) via #6 copper.
I'm still debating the spark arrestors. If I decide to use a spark
arrestor, I was planning -one- for the signal feed only.

Thanks again to both of you. The conversation is intriguing.

>
> Thanks,
> David, K4ZZR

According to most I've read, you would want all ground wires going to a single point on the bulkhead. You want all at the same potential. So according to some, even the bus is a bad idea. You would preferably want a seperate ground wire from each piece of gear to the common bulkhead. The bus is a daisy chain, and will not keep all at the same potential. As far as rf grounds, I wouldn't be overly worried about that. #1, if all your antennas are complete , you don't need a rf ground. And anyway, an rf ground wire will act different on each band, and you never know whats gonna happen. I would just treat the present ground wires as the rf ground, and forget it. The lightning aspect much more important. I don't use a rf ground at all, and it's never hurt me yet. Actually, I don't like rf grounds in the shack. They like to play antenna too often. The rf ground should be at the antenna if one is indeed needed. Say with a vertical etc. You don't need one at all with a dipole, or any other complete antenna. BTW, treat anything I say with a grain of salt, and get plenty of other opinions. There is a boatload of stuff in deja news. Also the usual lighting co's. polyphasor etc. MK

3923. Re: Crossed Field Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-11 08:36:36 UTC
From: Gray Frierson Haertig <gfh@haertig.com>
Message-ID: <3A349215.544C96C2@haertig.com>
Source record: 174872

Tom,

I find it interesting that by championing the independent tests that you clearly state should have been done ten years ago, I am characterized as being somehow duped by the inventor's of the CFA and completely unknowledgable. The clear implication, though please correct me if I am wrong, is that you think I am a fool for this.

It appears that you are unable to differentiate between my support of the tests and support of the antenna. As I have repeatedly stated, I will be very surprised if the CFA lives up to the claims of its inventors, but I fully support the tests that are currently under way. If the proponents of the CFA somehow stymie the investigators in their tests, that is what will be said in the report and no conclusions drawn. If the the investigators have full access (which they have been promised) then their report will reflect their results and conclusions. Isn't that how it is supposed to work?

As to making measurements at 450 MHz, I will bow to your superior knowledge about the workings of the CFA. Perhaps it wouldn't be the thing to do. Though, since I was in no way attacking you I would appreciate being told this in a civil manner and not being attacked.

As to whether measuring the elevation pattern is important or not, how do you determine skywave performance of a MW antenna without knowing the elevation pattern. And if you decide the elevation pattern IS important, how do you determine what it is - in any antenna, not just the CFA? How is it currently done? How can you determine the elevation pattern from the A-B test that you propose?

Bill Aycock takes me to task for speculating in advance of the tests what might be interesting avenues of research after the results of the tests are known. As I've said, I find idle speculation amusing, so I probably will continue to engage in it. It seems as if some consider any speculation or discussion as some sort of fraternizing with the enemy.

I don't think of this a a great moral battle between good and evil. I don't fear that Maxwell's laws will be struck asunder just because some folks are trying to make some money off some broadcasters (which they seem to have done). I am not part of a great electromagnetic army marching to war to protect electromagnetics as we know it today. I'm sure Mr. Maxwell's fine equations will continue to protect themselves quite well without any help from the members of this NG, as they have for the last 150 years or so.

In fact, I don't care a whit if the CFA's inventors are snake oil
salesmen of the highest rank, all I really care about is how this
proposed antenna performs, so I can decide for myself if it is of any
use to my clients.

God willing and the ether don't rise, we will soon have sufficient grist
to keep our mills safely away from the dangerous waters of premature
speculation (to mix a metaphor or two). Besides which, don't they have
drugs now for premature speculation? (c:

Gray

P.S. The name is Gray, not Gary. Gary's the one that doesn't belive
that there is power in transmission lines. (c:

Mike,
I beleive that the Resistor is about 390 ohms or close to it.. It might be
suitable for termination of a Beverage Rx antenna of some sort.

> normally have these.

I have taken a closer look at Reg's observation of the pi-L network, using Radio Designer and Matchcad.

In several examples I could see a minor "hump" far below the desired resonant frequency. The frequency response of this hump was about 3 dB down and the impedance at the second hump was about 1/4 the resonant impedance and was highly reactive. The minor hump is not due to two-resonator coupling, but due to the way that the various reactances vary and can partially offset each other over some frequency range. At the correct peak the return loss is more than 50 dB, but at the false hump it is only about 3 dB (not very good).

If you tried to tune and load the PA at the secondary hump you would quickly see that it was not the right tuneup.

You may assign the problem to the radio, but... unless you are the manufacturer of the radio, or into extensive modifications of its' auto shutdown SWR sensing circuitry, you simply cannot assign the solution to the radio, heh, heh. Gotta assign the solution to the problem to another device...

Gray:

I applaud your open mind on CFA testing, but... a lot of folks may spend a lot of time and money for naught trying to prove that pigs can fly...

A similar circumstance is the everlasting perpetual motion machine.

I ask, should the US Patent office spend the hardworking taxpayers time and money, refuting, and proving incorrect by expensive experimental tests, the claims of each and every perpetual motion machine inventor, all in the spirit of keeping an open mind on experimental testing?

Or... is it valid to invoke Sadi Carnot's "Second Law of Thermodynamics", and throw those inventors and thier infeasible inventions back into the sea?

What?

From: Ole Dam <ole.dam@get2net.dk>
Message-ID: <Kp4Z5.88$8f.2844@news.get2net.dk>
Source record: 174877

Can anybody help me; I have an 18 AVT/WB which works perfect. Now I want to build an extra element for 18/24 Mc into this antenna - but how?? Shal I substitute some of the original elements or how? I have written an email to the Hy-Gain Company but get no answer.
Any help will be much appreciated.

Cecil asked the right question. You want sky wave or ground wave?

For sky wave you only need 1/2-wave antenna elevation for near optimum performance, if you are in the clear. That would be only about 10 feet.

For line of sight communications along the ground, the horizon is about 5 miles from an elevation of 10 feet. The horizon in miles is about the square root of twice the elevation of the antenna in feet.

So, for local communications, you need a lot of antenna height to communicate line of sight over long distances because the earth is curved and obstructions tend to interfere.

Best regards, Richard Harrison, KB5WZI

>
>Bill W0IYH

What has been overlooked in this thread is the fact that in a real (actual)
pi-net tank for a PA, there are more than three reactances in play. The tube
itself has some internal inductance and some output capacitance. Then there is
the inductance of the plate choke and the inductance of the connecting lead
(parasitic choke) to the plate tuning capacitor, the shunt capacitance of the
inductor to ground, et cetera........

True, at 160 meters the effect of these is minor but at 10 meters, they maybe be
significant.

>unknowledgable. The clear implication, though please correct me if I am
>wrong, is that you think I am a fool for this.

I think anyone who spends time arguing about something that is
obviously so out-and-out silly is being foolish.

If a person doesn't understand the physics, he only has to have enough
street smarts to add two and two, and see if it comes out four.

Can you honestly imagine the Wright brothers having a "flying
airplane" for ten years without letting anyone else see it fly?

Here is an "invention" so special it fills all the desires of
"something for nothing", yet the inventors instead of being on the
cover of Broadcasting have now degenerated to selling copies of how to
build the thing to foolish Hams over the Internet.

The CFA reminds me of the 500 MPG carburetor that Exxon bought and hid
so they could sell more oil, or the 500 mile L-88 Corvette who's Viet
Nam era owner died in the war and their mother doesn't know what it is
worth and is now selling at a garage sale.

People need to use a little common sense.

Basically, the same as an inverted v. The lower the antenna (in terms of wavelengths) the more difference between the two.

Why don't you download the demo version of eznec and see EXACTLY what the differences are?

3941. MFJ antenna analyzer, NG on Diamond ant.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-11 15:55:55 UTC
From: n1kk@netzero.net
Message-ID: <912te7$e97$1@nnrp1.deja.com>
Source record: 174890

I have recently installed a Diamond V2000A vertical for 6,2,and 440.
I connected my MFJ model 259 to look at the SWR on 6 and 2 meters
and it made the antenna look like it was resonating out side the Ham
bands. After several attempts to adjust the 6 meter tunning adjustment
on the V2000A I finaly gave up and assumed the antenna or coax was
bad.

I gave Diamond a call and told them of my experience. They asked me
what I was using to measure the SWR and I told them. I was told
the MFJ analyzer will not measure the correct resonant freq of
Diamond antennas and he sugguested I try another meter.
I tried my bird 43 and sure enough he was right as the antenna resonated
right in the middle of the bands.

I would like to hear some techincal disscussion on how this could be.
My only thought so far is the MFJ does not represent a 50 ohm source
and has altered the resonance of the antenna.

I think this needs to be put into proper perspective. Tom is pointing out that none of us have enough information to make a rational decision regarding this one dispute between a vendor and purchaser. Mosley has been in business longer than I have been a ham, and I have used their products since the mid-sixties. I had a minor problem with a Pro-57B, but it was my fault for mis-interpreting the instructions, and Mosley thankfully bailed me out through their tech support. It should also be noted that they are a military supplier, which means their quality assurance system has to be in accordance with DOD standards. Mosley has antenna ranges that most of us could never manage, and if they say the antenna in question meets specifications after testing it, then I would be willing to take that to the bank. Obviously, there is something going on here that is out of the ordinary, but there are always two sides to every story, and we have only heard one side. No company could remain in business for over a half a century if they treated their customers like it is claimed.

No facts have been overlooked. The thing that is being discussed at the moment is just the basic pi-L network itself as shown in its basic simulations. If all of the other contingencies that can be imagined are added it is no longer "just" a pi-L network. These other items conceal the thing that Reg is interested in at the moment.

Current radios is what they is and their limitations are published, well known and they work fine within their limitations. The problem belongs to the hams who (a) believe and/or fail to understand antenna advertising and specs (b) don't have enough technical smarts to get a radio working into an antenna unless the antenna manufacturer hands them a PL-259 which provides a 2:1 SWR or less. Make that 1.3:1 or they get upset (c) show up for Field Day with new, untested antennas still in the box and without any antenna tuners or antenna instrumentation. They were not newbies and there was a bunch of 'em trying to muddle thru the problem. Which was them.

Except that in Reg's original post he asks:

>"Never having used such a circuit I wonder whether the double
>humps cause confusion or doubt when tuning up using the
>minimum-dip method. Or any other method.

>I should be interested to hear from any experienced users of
>the network how it behaves during tuning up. Is it just as
>straightforward as the ordinary tank or Pi network ?"

So how do you figure that the points that I raise "conceal the thing that Reg is
interested in at the moment?" Seems to me that (incomplete) Radio Designer
simulations, Norton Transforms, MIT profs, et cetera, "conceal the thing that
Reg is interested in at the moment."

So far the only one that answered the question was Mark, NM5K. Everybody else
(unfortunately including the undersigned) failed.

This thread is another victim of topic drift.

That's very strange!
I've never used my analyzer with that antenna, but it sounds strange. Maybe
your analizer is out of order. Try with a 50 Ohms dummy load and read the
meter: you shoud read 50 Ohms and SWR 1:1.

You are obviously confusing energy efficiency and RF efficiency. It is
100% RF efficient. It is 10^-37 percent energy efficient.

Exactly.
The point that should be made is that an antenna 1/50 wl with no radial system is great - as compared to no antenna at all. Trouble is, proponents of these small antennas make outrageous claims. When you don't have the space for a full size antenna, you have to shrink the antenna to fit, by one means or another. To me, there are two categories of valid arguments against these antennas: 1) arguments against outrageous claims. Your post containing the statement above (laughing at those claims) is in that category. And of course, you are correct. 2) arguments that compare one form of "shrunken" antenna to another are also valid. By demonstrating a tremendous overall superiority of one "shrunken" antenna vs another, one lends validity to his point that "Antenna A is a joke". For example, I'd bet that an Isotron for 160 would beat a light bulb antenna, hands down, if for no other reason than the greater capture area it enjoys over the light bulb. But I would bet that a 70' tall 160 meter vertical would beat an Isotron installed at 70 '. In the first case (light bulb), a strong case can be made about the light bulb antenna being a joke. But in the second, the delta between antennas is not so readily apparent.

Do you mean you think there might be a market on the internet
for the special antenna wire I invented? It gives your signal a
range of 500 miles per inch. But there's still a bug in it. I can't
get it to work with any nearby stations.

All an antenna analyzer is is a low power transmitter. There are few reasons why it wouldn't work with ANY antenna made:

A) The analyzer has a problem; check with some fixed resistors at various frequencies.

B) The antenna is receiving external RF that "confuses" the analyzer detection circuitry (it is low power, remember).

C) The antenna is non-linear with power (not too likely, but possible with corroded connections and the like).

Take a look at the phased quarter-wave vertical patterns
in the ARRL Antenna Handbook to see what is possible. This
is a pretty complicated topic. Do you want to beam up/down
the road or phase the antennas for selectively directional
operation?

How did you measure the resonance of the antenna with your Bird Watt Meter?
Did Diamond tell you the antenna is resonate at 50 Ohms? Also, how would the
coax or the MFJ meter alter the resonance frequency of the antenna?

Scott McClements.

3970. Larsen or Diamond for 706 rig

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-12 01:03:50 UTC
From: Eddie Bryant N4UMJ <N4UMJ@carolina.rr.com>
Message-ID: <WPeZ5.34714$4K4.4972655@typhoon.southeast.rr.com>
Source record: 174769

I have an antenna dilemma on my car and the new
706 MKIIG I am about to order.

I am considering going with a single 2Meter/440
antenna on my vehicle to connect up to the new
706 MK IIG .

Currently I have two separate antennas.
A Larsen 5/8 wave 2 meter NMO-150 (3dbd) 49"
and
A Larsen 5/8 over 1/2 wave NMO-440 (4.5dbd)31"
antennas that I have been using on my Kenwood
Dual band TM-741radio.

As you probably know ,the 706 has a single antenna
connection for the VHF/UHF antenna.
This leaves me in the situation to use a Diamond MX-72D
(with a 0.15 db loss) duplexer to connect these two existing
antennas into one antenna port on my 706.

Or I have a choice to buy a single dual band antenna and
do away with the duplexer and an extra antenna.

I am looking at the
Larsen NMO-2/70 dual band 33.5"rated at 2.4/4.0 db gain
and also at the
Diamond NR770HBNMO 2M/70cm 38.2" dual band
3.0/5.0 db gain.

Is Diamond fluffing up their numbers or do they have a
better antenna ? Is the bigger (longer) antenna the better
choice here? Obviously db's should be the determining
factor here.

Curious to know what VHF/UHF antenna people out there
are happy with on their 706 rigs ?

Also had thoughts of just leaving my Kenwood TM-741
dual band radio in the car along with the newer 706 anyhow
but I like the idea of the 706 covering HF plus all the bands
my Kenwood 741 does now. That's another topic for sure.

Thanks for any input on this !
Eddie Bryant

:It seems Tom has a tremendous zeal for discrediting your plight. (?) Could
:it be that he has a portion of your investment? At any rate, Tom can buy all
:the antennas he wants from Mosely and nobody is going to stop him. Most of
:us, however, are more careful with their money and prefer to do business with
:more reputable businesses, being less daring to lose $$. Thanks for letting
:us know before we learned the same way you did, i.e., "The School of Hard
:Knocks" Respectfully, Stinson

I wouldn't be too quick to jump to conclusions. After all, you have only
one side of the story. It is also interesting to note that there have not
been a bunch of others following up with problems of their own. To me, this
says that it was an isolated incident - regardless of whether it was
reported accurately or not.

Mosely has been in business for half a century or more, and millions of Hams
have purchased their antennas over the years. I personally have used several,
and have always had good service when the rare problem occurred.

The answer is not simple. It depends on spacing and phasing of the
antennas. It is also possible that you may need other than RG6 coax
when you "co-phase" the antennas, especially on the run from the rig
to the phasing harness.

I believe there is information in the Radio Amateur's Handbook. I know
that there is information in one of the ARRL Antenna Books.

: right in the middle of the bands.
:
: I would like to hear some techincal disscussion on how this could be.
: My only thought so far is the MFJ does not represent a 50 ohm source
: and has altered the resonance of the antenna.

Would you believe that both meters may have been correct?

I assume that, when you used the Bird meter, that you were tuning for minimum VSWR. If so, that probably is not at the resonant frequency of the antenna.

As an example, a 1/4 wave vertical may have an RF resistance of about 30 ohms, when mounted in a given location, at resonance. Now, the MFJ should show that 30 ohms and the resonant frequency. If you use the Bird meter, you need to get to a 50 ohm impedance before it will show a 1:1 VSWR (if it is even possible to get there). This will NOT be at resonance for this particular antenna setup.

>n1kk@netzero.net

Hi Ken,

How far was the MFJ analyzer from the antenna?

Did you use the same coax cable and how long was the cable?

Was the antenna when measured with the Bird in the same exact
location?

Some antennas have a lot of common mode current on the feedline, and
give conflicting results because of what is hung on the cable.

There is absolutely no reason, other than an antenna defect or a
defect in the analyzer, that the reading should not be similar or the
same.

Much to my dismay and discomfort, I found that a good ground system at the tower/antenna does not protect from the household current getting tied to the tower, or antenna.

I figured that the coax shield would tie the two systems together. Actually a short in the rig (Yaesu FT 101) put 110V AC on the coax braid. (this was before ground fault connectors/detectors)

I discovered the short when I picked up one of the radials that had come loose the previous winter, under the vertical antenna and knelt down to stick the outer end back into the ground. I felt it should be safe as the thing was tied to a ground rod at the base of the antenna.

When my knees touched the ground, that sucker really grabbed.
Only when I rolled backward and my knees cleared the ground was I able to let go.

The system needed a good heavy gauge cable tied between the grounds.

BTW...This was back in the 70s.
The current system is a 90 foot tower with a tribander and TV antenna. The ground system is 8 to 10 ground rods (I've forgotten just how many as they've been in there for close to 12 years or so.) All the rods are tied together with #2 bare coper wire which is cad welded to the rods.

That tower has taken three direct hits over the years.
The rigs are rarely even turned off and I've only lost the front end out of a Kenwood 221 2 meter rig and about 130 feet of 7/8ths Heliax. OK, so the antenna (Diamond 144/440) was more than a bit frazzled on the end and it removed all the electrical tape and plating off the coax connectors up there. There was a repeater hooked to the other end of the Heliax which suffered no damage.

The new tower has been hit at least twice with no damage to anything yet. However those hits didn't shake the whole neighborhood like the ones to the old tower. There was no damage to either tower. The new tower didn't have any ham antennas on it yet.

3979. Wermager K0EOU sloper

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-12 05:42:25 UTC
From: dcoffey@mindspring.com
Message-ID: <3a35b773.460246459@news.mindspring.com>
Source record: 174778

I'd like to install a Wermager sloper for it's broadbandedness on 80M. The 15th edition of the ARRL Antenna handbook only shows it installed with a tower for the vertical leg. I don't have a tower, so I'd like to install it with a wire, or a group of wires as the vertical leg. I wonder what that will do to the antennas broadbandedness. Also, I wonder how this antenna behaves on other bands, when cut for 80M, but used on 160, as well as higher bands, with a tuner.
The Wermager sloper is essentially a horizontal vee, legs about 54 ft each with 8-10 ft separation between the ends of each leg and a height of 8 ft (very close angle). The apex of this vee is connected to the center conductor of 50 ohm coax at a height of 15 ft. Then there is typically a tower, 35-50ft, with a sloping wire of about 78 ft coming from the top, to within 10 ft of the ground on the low end. This leg is electrically connected to the top of the tower. The braid of the feedline is connected to a tower leg at a height of 15ft. It is said to give 1.4:1 or less across the entire 80M band.
I'd appreciate any info, experiences with the ant, etc.
Thanks,
WA4YYQ Dennis

I went with a Diamond UHV-8 (think that part # is right). I'm happy with
it, knowing up front that I'm compromising no matter what for mobile HF.
The first time I keyed up on 10 meters, I got a call back from Peru - and I
was parked in my garage at the time and had not even fine-tuned the whip!/.

Does very well on 2M, too.

But it is tall - about 4' over the roofline, mounted high on the hatchback
lip of my Explorer.

Leave 'em right where they are ;-)

The whole question of resonance is a big unknown and may kill any attempts I make. I didn't plan on lugging a big 'ol tuner along, just maybe a length of ladder line to fool around with.

I live here in the bay area, and as much as I personally like the idea, the local constables sure won't. The bridge may have a lot of metal, but it's grounded, so you'll have a nice ground plane and that's about it.
You would be better off bringing a dipole up to Mt Tam in Marin (across the GG Bridge from SF).

The EZNEC files are written in a BASIC data format so you have to know
the order and data type of each entry. Please contact Roy, W7EL, for
information.

Lots of ham towers are also grounded but that doesn't keep
those hams from gamma feeding their towers and using them
for vertical antennas. I can almost guarantee that between
ground and the top of the supports, there is a 50+jX feedpoint.

Thank you for the info, I have been using a 2 meter array for years that is all grounded and now I find out it can't work. Please don't tell the antenna, as it thinks it does and I wouldn't want it to find out differently.

Hi Jerry, Cecil,

It would probably be simpler to read the files into the demo version
of EZNEC and observe the details there. The built in limitations for
the free version may impose some problem however - maybe not.

Roger,

What you describe is precisely why the NEC rules were put in place.
Repeat that experience to other hams, *often*. I can't tell you how
many hams put up antennas without paying attention to (or perhaps
without knowing about) the NEC. I'm glad you weren't badly hurt.

The NEC could care less what happens to your equipment. Protecting
your *equipment* is not its purpose. The purpose of the NEC is the
practical safeguarding of people and property (not equipment) from
hazards that might arise from using electricity. The exact wording is
found in NEC 90-1. The NEC provides for safety ground - as opposed
to RF ground or lightning ground for towers.

It sounds like your lightning grounding has worked well for you!

Aside from the issue of RF ground or Lightning ground, you must
also bond those electrodes to the house grounding electrode
system, per 1999 National Electrical Code article 250 - 50, with
the proper sized bonding wire as specified in 250-66. There's
also code requirements for how to install and connect it.

OK, Now that I have my mag mount for my HF antenna grounded to my van.
When I use my HF radio it now causes interference on my two meter rig.
This has NEVER been a problem before adding the ground wire from the mag
mount on the HF antenna to the luggage rack.

Any ideas as to why?

How to resolve the problem?

Thanks for the response to my original question.

For that matter, I suggest buying a copy of EZNEC. The demo version will let him look at the files, but its limitations really don't let him do much with them. EZNEC is a reasonably priced program and worth every cent, IMHO.

Oh, I would be willing to convert them to NEC for him with my PRO version of EZNEC.

Source record: 174815

Yes, the best method would be to download the EZNEC 3.0 demo from
http://eznec.com. With the demo version, open the file, and you'll be
able to see all the details, as well as a graphical depiction of the
antenna. If you want to save the dimensions and other information in
ASCII format, open the Outputs menu at the top of the Control Center
(main window), then select Show Description. The ASCII display shown
there can be copied, saved, or printed.

You should be able to view any EZNEC file with the demo version. It'll
just refuse to do any calculations if there are more than 20 segments.

There are patents existing on very short-range induction-based communication links precisely because they DON'T radiate EMR and thus explicitly exclude communication over distance. That might be food for thought when considering the validity (or invalidity) of CFA technology.

Rick K1BQT

4018. QUESTION: Can shortened radials be effective?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-13 03:10:15 UTC
From: jason_hsu@my-deja.com
Message-ID: <916pak$l2k$1@nnrp1.deja.com>
Source record: 174817
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx

How small can a ground plane or radial system be and still be modestly effective in providing the "missing" half of a vertical monopole antenna? Has anyone here had experience with this? I am considering buying a Texas Bugcatcher or MFJ-1621, and I cannot bite the bullet until I can resolve this sticking point.

My questions:
1. How can a Texas Bugcatcher antenna be effective at 80m as a MOBILE antenna when 1/4 of a wavelength is 65 feet? Only semis are this LONG. Even the giant station wagons and land yachts of the early 1970s are barely 20 feet long (7.6% of 80m). NO vehicle is even close to being this wide.
2. How can a mobile antenna be effective if it is not mounted in the middle of the roof or trunk? Doesn't this mean that the antenna has less of a ground plane to work with?
3. Can I provide a ground plane with a few sheets of metal or wire screens? Has anyone tried this with a vertical antenna?
4. If inductive/capacitive loading, special coils, or helicity can allow vertical antennas to retain their efficiency at shorter heights (albeit at the expense of bandwidth), can these same techniques apply for radials as well?
5. How can people work 160m when even 1/4 of a wavelength is 130 feet? I know better than to think I can work 160m, but this would give me clues on how to work 10m-40m.
6. How can a tripod work as a radial system or ground plane for an Outbacker antenna? Isn't the tripod much too short?

Some signs of hope:
1. I read in the ARRL books _Vertical Antenna Classics_ (page 104-107) and _The ARRL Antenna Book_ that respectable performance can be achieved with radials as short as 1/16 of a wavelength. On the 40m band, this is barely 8 feet.
2. I read in _The ARRL Antenna Book_ (page 6-26) that some hams have reported good results when using helical radials. This would make HF operating possible for indoor antennas.

NOTE 1: My ability to operate HF from a crummy QTH (ground floor apartment with NO bushes or trees available to hide anything) is at stake.

NOTE 2: The future of ham radio is also at stake. If I can operate 10m, 12m, 15m, 17m, 20m, 30m, and 40m in the face of my bad QTH, I can easily recruit and even elmer new hams.

NOTE 3: No, I don't expect to win contests, bust pile-ups, or earn my
WAS with lightning speed.

> 1. How can a Texas Bugcatcher antenna be effective at 80m as a MOBILE
> antenna when 1/4 of a wavelength is 65 feet?

The vehicle and the antenna become an antenna system. The antenna coil
makes the antenna appear longer than it really is. The vehicle is a
fat element. The antenna system is somewhat off-center fed.

> 2. How can a mobile antenna be effective if it is not mounted in the
> middle of the roof or trunk?

Consider a dipole with one leg parallel to the ground. The leg parallel
to the ground is the vehicle. On the higher bands considerable gain
can be had in one direction with a bumper mounted mobile antenna. A
normal vehicle is about 1/4WL on 17m. A rear bumper mounted 17m mobile
antenna exhibits some gain toward the front of the vehicle.

> 3. Can I provide a ground plane with a few sheets of metal or wire
> screens? Has anyone tried this with a vertical antenna?

Bury an old vehicle? Seriously, whatever ground plane you come up
with will be improved by at least one resonant counterpoise. When
camping, I sometimes attach a resonant counterpoise to my pickup.

> 4. If inductive/capacitive loading, special coils, or helicity can
> allow vertical antennas to retain their efficiency at shorter heights
> (albeit at the expense of bandwidth), can these same techniques apply
> for radials as well?

The answer is yes but loading does NOT retain efficiency. Shortened
antennas are simply less efficient than full size antennas.

> 5. How can people work 160m when even 1/4 of a wavelength is 130 feet?

The longer the wavelength the less the efficiency of a mobile antenna.
A 160m mobile antenna may be less than 1% efficient while a 10m mobile
antenna may be 75% efficient.

> 6. How can a tripod work as a radial system or ground plane for an
> Outbacker antenna? Isn't the tripod much too short?

Yes it is and it doesn't work worth a darn especially on the lower bands.

> 1. I read in the ARRL books _Vertical Antenna Classics_ (page 104-107)

This is especially true of buried radials.

I have a KLM 2m 14C circular polarized yagi I am trying to refurbish to get
going
for AO40 operations....HOWEVER, all the 3/16" solid elements have been damaged
beyond repair......the boom , and driven elements are intact. I also
think KLM has gone out of business. Does anyone know where I can get
replacement elements for the KLM 2m 14C yagi?????? Any help will be
appreciated.
Thanks,
John / WA5DGH

There's nothing to stop a person from feeding the eggbeater vertically
though. Easily done. Just feed from the side instead of the bottom. It
should work fine for fm stuff. Also to the orignal poster: I'd just
stick up a 1/4 wl GP as a start. It will do ok for average use. Easier
to set up than the eggbearer. The eggbeater will need twin crossed loops
and a phasing line. The eggbeater does have a real omnidirectional
pattern, but so does the GP for normal uses. You can make a GP with a
so-239 and 5 pieces of stiff wire. Cheap and easy. MK

4022. Help - Identify the model of Hy-Gain HF Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-13 04:14:04 UTC
From: Raj Narayan <raj_narayan@satellite.bigpond.com>
Message-ID: <KzCZ5.157697$e5.113517@newsfeeds.bigpond.com>
Source record: 174721

Hi,
Can someone please help me identify the model of a Hy-Gain Multiband HF Vertical Antenna. I have just narrowed it down to Model 18V or DX88. The vertical is a 80-10M and have the following markings on the black cans (Traps, I guess):

- 80 40 M ASSY
878532 HY-GAIN 1991

- 10 12 15 M ASSY
878204 HY-GAIN 1991

- 30 M ASSY
878536 HY-GAIN 1991

- 17 20 M ASSY
878202 HY-GAIN 1991

Any help identifying the model (and, if possible, an electronic copy of the manual for reassembling) will be greatly appreciated.

> Alan KB7MBI in Woodinville, WA

It can make a difference. I have a Z dipole at 42 ft I've been using for
a couple of years. It's good close in out to maybe 500 miles, but pretty
lousy far off. I also recently put up a inv L to try to get a little
more vertical operation. I can tell a fairly good difference on most far
off stations. Sometimes up to 2 s units.
"no particular db difference implied". Also listening to most BC
stations I see the same. I may convert the L to a T later to try to cut
a little more of the horizontal radiation. But I do find the dipole is
good close in , say around the state. About the same type thing as 75m,
except my 160 ant half the height in wl so even more of a burner. More
ground loss too unfortunatly...You are doing pretty good to get out with
2 watts. 160 can be quirky. Sometimes I hit people 20 over 9, and the
next guy can't hardly hear me at all, even though I may hear him fine.
You never know. Depends on what they are listening with too. I only run
100w on 160 so not much juice, but far easier than 2 watts. And both my
antennas full size. So you couldn't be doing too bad. If I were to run a
B/W on 160, I'd short the thing together and run as a vertical most
likely. MK

Your car body has a significant capacitance to ground, which becomes part of the antenna system. Trust me, it works great. Your problems if any, will be with the whip part, not the ground part. Just put up a well built, resonant, impedance matched whip and you'll get out amazingly well. Even lousy, lossy antennas work out hundreds and thousands of miles. Try it, you'll like it!

The relatively enormous capacity between a vehicle frame and body
couples the ground return of a mobile antenna to actual earth ground,
and there is where the antenna return current is collected. At lower HF
frequencies, the vehicle (even a large motor home) provides little of
the radial structure ("ground plane"). At 10 meters a large vehicle can
be effective as a ground plane by itself, although there is still the
large vehicle/earth capacitiance in place with even lower reactance than
at lower frequencies.

I feel that this frequently overlooked aspect of mobile antenna
operation answers a lot of questions.

It should be running to the bulkhead. It appears that you are using it
for your common tie point.

Separate ground rods would mean there is some resistance between your
equipment grounds and the tower/bulkhead ground - not desireable.

Actually Chuck, it does help.

Please proceed with consulting your attorney and your suit. I will continue to keep the readers informed.

Your statement is mendacious. To clarify, it is in direct contradiction to your statement of two years ago.

Under no circumstance will I apologize for being truthful.

Here is my address for your attorney. All mail must be sent registered.:

2 Ledgewood Place
Belmont MA 02478.

I hope that this will end the last vestiges of personal attack and jealousy that you and others have expresed here on this NG. Getting an attorney and reviewing your PUBLIC statements is a very positive move in keeping this NG sane--as we have seen in recent weeks (for a change).

I hope that your irrational response--quoted above--- also provides the public with a sufficient calibration for your other statements.

Nathan Cohen, Ph.D.

4035. Re: Grounding Mag Mount - PART TWO

Newsgroup: rec.radio.amateur.antenna

I have tried NOTHING, This has been a problem for only a few days since grounding my HF mag mount.

Should I try to figure out if it is comming from the antenna or power wires?

4036. 10M Contest and Fractal Quad Yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-13 13:07:08 UTC
From: fractenna@aol.com
Message-ID: <20001213080708.22169.00005021@ng-da1.aol.com>
Source record: 174734

I had a wonderful time with the 10M fractal quad yagi this past weekend! I am using hand logs so there is a bit more work in duping and checking. But my tentative score is over 1500 QSO's and about 125 multipliers. That puts me at approximately 375,000 points for SO SSB LP.

There is a very good chance I 'made the box', based on reported claimed scores on the 3830 list.

Unfortunately K1KW and Yuri didn't take on my constructive challenge. I stated that I would have no problem beating them. I think my point is made though : at this time there is a good chance I came in second in the country in this category(after N4OX).

I am disappointed that K1KW now is pursuing a lawsuit and acting publicly in an embarassing fashion. All I can say is that I tried to get him to focus on something constructive by challenging him in the contest.

The fractal quad yagi can be found on the ham page of:

http://www.fractenna.com

In coming weeks, this and other hams stuff will be moved to a new URL, which I will apprise of shortly.

Best to all,

73

Hello Tom,

My statement about Cushcraft non acceptance of RF Bridges, aka MFJ Autek, AEA for SWR measurements, could be checked on their site in technical support branch-manuals. Manual for R6000 states this but not the manuals of R7000, R7 and R8.
Best regards,

Nermin S58DX

> (albeit at the expense of bandwidth), can these same techniques apply
> for radials as well?

yes, if elevated. If buried, there is no need to do this. One trick I've
been trying lately on 160 is to use radials that don't touch the earth
but are supported off the ground a couple of feet. I have two full size
160 radials layed out in this manner in addition to my other
grounding.Also a few shorter radials. Seems to do ok for the small
amount I have out. I'm also tied into everything else grounded around
here. Even a chain link fence on the side of the yard. I'm using two
antennas on 160 now, a Z dipole, and an inverted L. I was on last night,
and as is usual close in my dipole almost always wins. But if a far off
guy comes in this can change fast. A guy in Wichita KS came on last
night while I was talking to a guy about 80 miles east of here. Of
course to him, the dipole better, as is straight up and back down, but
the guy in KS gave my inv L about a 6-8 db advantage. He was far enough
that the increased lower angles that you get from the L come into play.
The dipole is horrible at low angles. So even though in theory the
dipole is more efficient than my L, it doesn't always matter. It matters
more what angle you need and what the antenna does at that certain
angle. This is why many times a mobile can do real well on the low
bands, even if low efficiency. What it does do is where you want it. Or
at night anyway. This same factor is why a mobile is so lousy at high
angle stuff in the early evenings. It's not radiating at the angle you
want for that time of day.
> 5. How can people work 160m when even 1/4 of a wavelength is 130 feet?
> I know better than to think I can work 160m, but this would give me
> clues on how to work 10m-40m.

You would be surprised. I work quite a few 160 mobiles from time to
time. I worked one the other night that was driving thru KY, TN etc. I
think he was running about 300 watts if I remember right. He was doing
quite well. Actually, better than some home stations with crummy
antennas. Sure the efficiency is ultra low, but it will still work quite
well. The angle of radiation from those antennas is just about what you
want for 160m, so they work ok. MK

Yes.

>tell you what you should have learned by doing the exercises.
>(They should also tell you what you will learn by doing the exercises
>at the beginning of the section.)

Sure. Those are all fine and good. But _how_ it is done is just as
important.

I have NEVER seen a real textbook contain phrasing such as the
condescending phrasing found in the ARRL book:

>> >> >[If you worked all of these problems along with the text, you should have no
>> >> >trouble with the phase-angle questions on the Advanced class exam. Just

A non-condescending version would read:

Everything you need to know to solve the phase-angle questions on the
Advanced class exam has been covered by the problems in this text.

Or:

The problems along with the text illustrate all you need to know to
answer the phase-angle questions on the Advanced class exam.

(both are a simple statement of fact)

Or even:

If you understand how to work all of these problems along with the text,
you should have no trouble with the phase-angle questions on the
Advanced class exam.

(that is an opportunity for self-assessment)

But:

If you had worked all the problems ...

Or:

If you had read what I've written ...

Are both equally condescending.

>condescending, as you have stated. Context makes a big difference!

Not as big a difference as phrasing. My context was as an example.
The ARRL context was to introduce a "checkpoint." Both are equally
condescending.

Mr. O'Neal:

My attorney has advised me that your statement regarding our private phone
conversation being-- taped-- is in violation of federal and Massachusetts laws

and statutes. At no time did I in any way agree to such a recording. In addition, at no time was I aware that our conversation was being recorded.Your offer to make this private conversation public is in violation of state and federal law. You have also broken privacy laws and federal and state wiretapping laws if such recordings were made.

I will persecute to the fullest should you actually have in your possession this illegal record.

Nathan Cohen, Ph.D.

Yeah, ME. Pizza cake. I can't bury anything because the macadam driveway goes right to the brick wall outside my window. So I drilled 1/4 inch holes in the mortar between the bricks and ran a 100ft counterpoise six inches above the macadam via little plastic anchors and screws. I also wander around the parking lot with a very lethal 65 Lb. pull compound bow shooting wire into trees at will. Got a Larson 2m gain vertical bolted to an upper level balcony. There are two "tricks": (1) All conductors, hardware and cables are small and rendered flat black (2) Understanding that people, particularly apartment dwellers don't have a clue about wires or compound bows plus they could care less about what goes on outside. Which leads to the bottom line: Balls makes things happen, paranoia does not.

M2's Log is from 10-30MHZ. It also has 7MHZ but "SKIPS" 8MHz and 9MHz.

The Tennadyne are continuous from 13MHz to 30MHz; not 10-30 like the M2.
And you don't get 7MHz.

While Tennadyne may make an excellent product, I can't speak about them
as I have no experience with them.

M2 is designed by Mike Stahl who also was part of the KLM team that
designed KLM's Log (which has a great reputation). The M2 version
is an improvement!

You can't go wrong with an M2 antenna. I'm sure that Tennadyne is
excellent too.

Why do you want a LOG? Just curious. if you are staying inside the
Amateur Bands, I would SERIOUSLY look at Force 12!

So,they're gonna add another 2000 footer here? There's a ridge about
15 miles east of Springfield, MO where there are *four* 2000 footers
lined up, with a 1000 foot shrimp nestled between.
One TV station just built another 2000 footer near its original,
evidently for its new HDTV system (maybe that's the one mentioned in the
posted URL).
Dunno what they will do with the original. I can't imagine them taking
it down.

Seems like the bridge would work better as a toploaded short vertical at VLF. With the suspenson cables as capacitive loading. Like an aviation NDB transmitter.

I like the idea of carrying the rig and a dipole up into the Marin Heights. You even have a shelter, in the form of some of the old WW2 gun emplacements still there which were built early in the war when an invasion from the Far East seemed likely.

Hi Dennis,

Remember is any slopper worked against a tower, the tower IS the other half of the antenna. Bandwidth, SWR and overall performance depend heavily on the tower providing a very low impedance for the coax shield.

At times the tower's common mode impedance is fairly low, because the owner often has a big yagi on the tower and maybe even a bunch of uninsulated guy lines or other things that act like a counterpoise.

On the other had, an empty mast or tower, grounded at the bottom and 60 feet or so tall, won't work at all with an 80 meter slopper because the top would be an extremely high impedance.

Sloppers are very unpredictable antennas, since the "other half" of the slopper is the tower or mast itself.

Keep that in mind when planning your system.

>operation answers a lot of questions.

That's right. The vehicle itself doesn't "like" to radiate except as
it contributes a bit to height of the antenna.

It really isn't much like a bent dipole at all, since most of the
current flow down towards the earth.

Small counterpoises (ever cars and trucks) never really make an
efficient ground system (except where the vehicle is large compared to
the wavelength), but as was pointed out you can work amazing distances
with very poor efficiency.

If you have a small counterpoise, the system is ALWAYS more efficient
mounted up away from earth as far as possible. The closer to earth
with a small counterpoise, the more loss the system will have.

Larger systems are non-critical to height, They can be buried,
elevated, or whatever you like and efficiency will remain high.

Not so with electricall small counterpoises, they need to be up and
away from earth and other lossy media.

Great suggestion!

The SB220 is about, oh, 60 feet away with with no connection to anything. In fact, its in the basement next to my dad's briefcase and other stored stuff.

How much farther away should it be?

And does entertaining your speculation mean that I have to freeze my tootsies because you think a heater fan is an amplifier fan??

Also, you can't argue with results, can you Tom?:-) Right now I am #2 on the 'rumored score' list:-) So its not a matter of shootin' ducks, or everyone would have the same number of ducks:-)

Jason, when you live in serverely antenna-limited circumstances you
gotta think outside the box. You might find that a "portable" or
"temporary" antenna system
will work best for you-one that you take out and set up before you use
it, and take down for storage when your operating session is done. This
means coming up with something simple, easy to assemble and disassemble.
Ther are a lot of people in your circumstances and therefore there is
a lot of work that has already been done in this area. You don't need to
try to reinvent the wheel, and don't expect to be able to install an
optimal antenna system. Expect to use a compromise simply because that
will be what is demanded of the situation. Searching among the
literature will procduce a workable antenna that will do reasonably well
and give you much operating satisfaction.
Ths StLouis Vertical is a multiband antenna that has gained in
popularity among hams for limited antenna quarters as well as portable
use. It's easy and quick to set up and take down, and you can use short
wires laid temporarily on the ground for the counterpoise. There is no
requirement to use 1/4 length radials, at all, for very effective
operation if not most optimam efficiency.
Wben travelling or camping, for stationary use, I use a 60 ft length
of wire, tuned with an autotuner designed for that use, attached
temporarily to whatever support I can find, never more than 10 feet off
the ground, and the counterpoise I usually use is a 40 ft length of
copper magnet wire about 22 guage, just laid on the ground. It works
well enough on 40 meters and up that I haven't looked for any better
solution. And I have used it effectivly on 75 meters.
Don't be misled into thinking that you have to follow strict antenna
engineering principles just to be able to get an effective HF station on
the air. Agan, you've got to think outside the box and use what works
for you in your situation.
You will find that consumer device RFI will almost certainly be a
problem with any antenna located inside or very near a residence, if
you're running any power level above 20-30 wttrs or so depending on your
exact circumstances. And liviing in a multiunit residential apartment,
you'll have to tolerate the TV horizontal scan frequency harmonics that

appear every 15,750 across every one of the lower frequency bands. ANy antenna system near a residence gets that. I moved ll my antennas to a tower 150 feet from the house and I now have NO RFI and NO TV QRM.

Carl Westerman wrote:
"I have a radiating AM tower and I need to install some celluar panel antennas on standoffs at the top of it."

Over 50 years ago I worked at a 5KW, 790 KHz station that had an FM affiliate in town, almost 25 miles from the AM transmitter. The FM call sign was appropriately KOPY, as it duplicated the AM program.

KOPY was our reserve studio-transmitter program line. Our FM receive antenna was atop one of the AM transmit towers. It provided an interference-free signal to feed audio to the AM transmitter on those occasions when the program wire-line was impaired.

The AM transmitter should be almost harmonic-free by FCC edict. Your UHF receiver needs enough selectivity to prevent front-end overload. This can be provded ahead of a well-shielded receiver even when the receiver itself is inadequate.

Another of my experiences with such interference comes from several years after the KOPY experience. I was working at the world`s largest HF broadcast plant, at the time. We were using 450 MHz relay for multiple simultaneous programs. The receivers were right inside a screened room of the broadcast plant. The antennas were mounted on a tower erected for the purpose right alongside the transmitter building. It worked just fine.

Someone else thought we could improve program fidelity by using FM broadcast transmitters and monitor receivers for program relay. They had the clout, so we did it. The government involved licensed it as they had no FM broadcating a the time.

Harmonics and their mixing products were disasterous. We just had too many high-powered SW broadcast transmitters operating on too many frequencies around the clock. The FM broadcast band was too close to the SW broadcasts and the receivers accepted a wide band slice of frequencies which appeared.

We were able to find a sweet corner of our nearly 500 acres to site the BC FM receivers where interference was no problem. So a house was built, power was run to it, conduit for the underground audio cables was installed between receiver site and transmitter building, a tower was erected for the FM yagis, and it all worked fine.

Sometimes, if it ain`t broken, you shouldn`t fix it!

You should be able to make the cell phone antennas work well on an AM broadcast tower. The coax will have no appreciable effect on the AM

broadcast tower. You can just wraplock the coax to the tower. A leg may be convenient for cable routing. You may want to mount your cell phone antennas slightly below the top so that they are protected from lightning to some extent. Solid connection to the tower at top and bottom will help avoid problems. You need to make a coax cable coil at the tower base to isolate the AM broadcast r-f, much as r-f is isolated from the a-c by tower lighting chokes.

Best regards, Richard Harrison, KB5WZI

Hello Carl;

This is not an uncommon situation. I've worked for several AM
stations whose tower doubled as a support for FM, VHF, or UHF
antennas. Assuming the AM antenna is series fed, the device
that you need is an isocoupler. These are essentially traps tuned
to the AM transmitter frequency which are mounted at the base of
the tower, and generally provide enough isolation for both systems
to operate without mutual interaction. They are available from
broadcast supply houses and some manufacturers of VHF/UHF
antennas. You should be able to work with the station's engineer
or your PCS company's engineering department to procure one.

If the isolation is not sufficient, you will end up with receiver
desensitization and transmitter intermodulation products which
could both severely degrade your system's performance and
potentially open you up to interference complaints from operators
of adjacent PCS, SMR, and microwave services.

A single tower omnidirectional AM transmitter facility is a fairly
easy case to deal with. However, If the AM facility uses a
multi-tower phased array, isolation becomes increasingly important
for the radio station since tower current phases and ratios must be
tightly controlled. The last time I checked, addition of any such PCS
antennas to a directional array required the broadcaster to submit
an FCC filing for antenna modification.

Good luck!

W.

Wrong again, fool! You clearly knew that you were
being recorded. It IS stated in the recording!, including the
recorder beep midway through with an explanation of
the answering machine having recorded us to that point.
The machine has a time out so the entire conversation wasn't
recorded. What a poor memory you have!

Do you actually need two different values of chokes (1-mH and 100-uH) or did you mean 1-mH or 1000-uH?

Mr. O'Neal--

Is there no end to your mendacity and libel? Which even now you continue?

PLEASE get an attorney and SEEK OUT his or her advice. I can guarantee they will ask you to stop your libel against me.

I do not wish to be your personal target: I cannot and will not add meaning or focus to your life. You need to move on to something constructive.

I tried to channel your obsession towards something useful--like competing in the 10M contest-- but you not only turned down that option but now obsess in other ways.

It appears a sad and spiralling situation for you.. Again, PLEASE see your attorney about this. I just can't help you Chuck, but I will defend that which is truthful and which I have worked for these many years: my reputation.

Nathan Cohen, Ph.D.

Chuck--

I am sure that I am not the only person here who wants to know more about your 6 dBd small beam which fits in a 1/8 by 1/8 wave form factor.

Specifically, could you provide some info on how you managed 6 dBd? It is possible to supergain on this form factor to get 6dBd. However, in doing so the impedance would change so rapidly as to make it useless at all but a very small passband--say 50 KHz on 10M. Also, the F/B is especially sensitive in such cases and is also highly monochromatic.

Is there a publication, or URL, you might refer us to so that we can learn more?

Rick--

I don't see how.

The CFA claims NEW PHYSICS to explain its alleged superior performance. I see nothing in the general area of invention you allude to which requires new physics.

The CFA does occasionally work better than a 1/4 wave . When? When issues of diffraction, refraction, ointerference, and vignetting come into play--all well known physics which is usually producing second order propagation effects. But no one HAS EVER demonstrated that the CFA has a higher gain than a 1/4 wave when propagation effects are excluded.

An isotron antenna takes advantage of the same propagation effects, and as a near point-source radiator can be useful--if you could CONTROL the propagation characteristics. Multipath isn''t always a bad thing.

Funny, but I don't think anyone here believes that an isotron antenna requires new physics.

So why should we BELIEVE that the CFA should?

"Don't F*CK with me..."--Chuck O'Neal

No Randy;

Chuck is obsessed, or at the very least, focused--with me as a target.. Over the last two years he has stated he will: ruin me financially; am on the verge of 'slipping up' and one more time and he's gonna get me; that I am a homosexual; and so on. On and on.

Now I see I am a 'fool', among other things.

What I expect will happen is that this and other recent post of his will actually take him to a place where he DOES get the advice of an attorney. After all, this is not the first time he has threatened me with suit. He did so sometime back. Nothing happened.

What his attorney will tell him to do is be quiet. Why? because he has made it clear==AND PUBLICLY== that I am a focus for him, and that his incentive to seek suit is not to make amend for any so-called (bogus) damage, but rather to destroy me financially. That is what he said: destroy me financially.

He also has a clear public record of libel against me. Which, unfortunately, he continues.

I have mixed feelings on this:Chuck was a bit of a role model for me as a young man, some 35 years ago. My memories are fond. That is the only thing that has stopped me from pursuing a suit against Mr. O'Neal (I am, after all, a good person).

I had hoped that he would, like the others on this NG, just drop his obsession and move onto other things.

Maybe that can happen, but it's not up to me.

In any case, I do hope he sees an attorney this time. I,myself, would like to stick with the fond memories rather than the bitter rantings of Chuck O'Neal.

Effective means that the thing does what it is intended to do -
it doesn't indicate how well it does that thing. So when you
ask "how can a ... be effective", you're asking, essentially,
how can you make contacts with a small antenna. You are
not asking about efficiency. Lets say, for the sake of argument,
that a 100% efficient antenna radiates 100% of the power
your transmitter provides - no losses. Let's further say that your
shortened antenna is so bad that it radiates only 1 percent of
the power the transmitter provides - 99 percent is lost.
Well, if your transmitter provides 100 watts, 1 watt is radiated.
QRP stations regularly have plenty of QSOs at less than a
watt. So that's how your antenna can be effective: in spite
of however crummy it is, it radiates *some* signal.

Now, in terms of electronics, how can your antenna be
effective. In order for it to do what it is intended to do,
it must be able to accept power from the transmitter
so that it can radiate it. To do that (accept power) it
must be a conductor (plastic and rubber do NOT make
good antennas!) All of the rest of it goes to the efficiency -
and that's the really interesting part. The other replies
have gone into that a bit where they mention capacitance,
for example. Essentially, your antenna is a tuned circuit.
Lets keep it simple: assume a 50 ohm transmitter and 50 ohm
coax. You want the maximum amount of power to transfer
from your transmitter to your antenna - that occurs when
impedances match. So - to get impedances to match you
design the antenna to have purely resistive 50 ohms impedance.
You do that by, among other things, introducing sufficient
capacitance to cancel out the inductance (or vice-versa)
at the design frequency. And that brings about discussions
of capacitance and inductance. Remember, this stuff goes
to the efficiency (how well it works) not the effectiveness
(whether it works at all) of the antenna. Any old hunk
of conductor will radiate if you feed it a signal. How well
it radiates is a function of its efficiency. I believe that
your question really implies efficiency.
By the way - all of the above applies in the reverse - to receiving
as well as to transmitting.

You'e gotten some good answers (as usual) from the
gurus, and there is a lot more they can tell you. With
antennas, it can be very important to closely define what
it is you are interested in - there are many interdependant

variables. I think their answers went to what you wanted
to know - they understood what your question implied.
Just be aware that when you discuss antennas it is quite
possible to get an answer that goes to precisely what
you asked rather than to what you really wanted to
know - or vice versa!

I'm not familiar with your antenna, but Home Depot sells
3' lengths of aluminum rod so if it's a typical yagi I would
think you could use it for the directors - if you have the
original dimensions. If not, drag out the books and figure
your own dimensions. Of course. that said, it'll turn out
you need 37", or Home Depot doesn't have 3/16" or
a host of other annoying details. But it's worth a try.

4092. am tower question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-14 00:59:54 UTC
From: carl westerman <carl@westcomgroup.co.uk>
Message-ID: <LMOZ5.8640$sK5.598407@news-east.usenetserver.com>
Source record: 174755

Here you go..

I have a radiating AM Tower and I need to install some cellular panel antennas on standoffs at the top of it.
Now I know that my copper coaxial cable will interfere with the radiation pattern of the AM tower and that I will have to get it working in sympathy of the am tower buy grounding the coax along the length.

Question?

AM is kicking out somewhere between 600khz and 1700khz.. I don't know what the power is but may be a kilo watt or less.
My cellular system will be at 1850mhz .. on maybe less than 100 watts...

I remembered I once used a 2m antenna very close to a CB antenna that when I transmitted on 20 watts it blatted out my cb signal... right across the spectrum on the analyser... even though the frequencies were apart by about 120megs...

How do you think the cellular tx / rx signal will be affected by this due to the sheer power and proximity???????

Also any other facts that I may have not realised would be appreciated.

Absolutely. Over the years I've become absolutely convinced that there is a
very rapidly diminishing return on investement associated with big "fully
engineered" antennas. I'm constantly amazed at what can be accomplished with
a bit of wire. My days of big towers and beams are long behind me, another
s-unit just ain't worth the work and aggravation.

This post sounds familiar...

At http://reality.sgi.com/192.82.208.21/byee_engr/slot_ant.html you will
find instructions on how to build a slot antenna out of waveguide.

From the page: "With a 16-slot total, the antenna can have 10-12 dbi gain."

Cap'n Mike, I guess I've done all kinds of crazy antenna things in the past. SWLing opens up more opportunities for creative thinking than does transmitting. Sure, to operate at peak, any antenna should be resonant on it's frequency of use at the moment, but it's not nearly as critical when SWLing (as opposed to transmitting). All that said, for SWLing, you may or may not have some of these options available to you but......
You can attach a lead-in wire to a rain gutter,

If you have metal frame windows, you can try clamping a lead-in wire to one window frame and run small dia. wire around the apartment to connect that frame to as many others as you can practically do. The wire serves as an antenna, with the added benefit of the metal frames with outdoor exposure. If you have screens, make sure you connect the screens electrically to the window frames.

If you're in something other than ground level, perhaps you can drop a vertical wire from a window, or better yet, maybe you can sneak a wire around a portion of the building, hidden under siding laps, etc.

If you have a balcony with a metal railing, connect a wire to that.

If you have more than one option available to you, use them all simultaneously. It's ok to have a wire out the window and be connected to a rain gutter.

Good luck and good listening!
Dennis

Source record: 174702

>"So don't f*ck with me..."--Chuck O'Neal

>So....fracky...do you want to try and dispute it? I will post it
>as .wav file if you do.

There is no wav file to post. That is why you have not posted it. Just like you didn't post, or e-mail, the summary of our conversation. (Remember; I asked you, politely, for this doc and you threatened to sue me?) And even if there is some 'file' --which cannot be what you say it is because what you are saying is false-- your attorney would be ill-advised to have his client initiate a suit when his client has broken federal law. If, as you say, you recorded our conversation.

I never, ever, ever, gave permission for you to record our conversation. I never, ever was aware that our conversation was being recorded. If I was aware of that, I would have asked you to turn off the machine.Furthermore, I am prepared to demonstrate that your experience in broadcast radio makes you more than aware of the wiretap laws and requirements of taping notification; that your broadcast radio background makes you aware of the techniques which can be used to fabricate a tape which sounds like the other person was co-recorded with said 'beeps' , and so on.

Also, it WILL be part of my evidence
>in the suit. Get your lawyers ready....What is your net worth?

This is the clincher. It is clear that your intent is not some 'correctional' desire (not that there is something to correct) but a mere nuisance suit -- where you have publicly stated your objective is to diminish my life savings, all that I have worked for as a working person. Ask your attorney whether the law sympathizes with suits in order to drain the resources of an individual.

Also, ask your attorney how such a public admission makes you liable and in a weak position for a countersuit.

>
>This effort of your's will be forwarded to the appropriate individuals.

The only 'appropriate individual(s)' is your attorney.I strongly urge you to bring this to his or her attention.

>
>hope this helps...
>with all best regards,
>Chuck K1KW

It does Chuck. Again, that is my opinion.. ANYTHING you do that gets you to take responsibility for your actions AND STOP HARRASSING ME is very

constructive. Even if it wastes $300 of your money having your lawyer write me a letter (which I will reproduce here).

That is why I will pledge to make daily effort to exhort you in this, as long as you continue to send harrassing and libelous replies.

So please: SEEK COUNSEL. That is the ONLY way you will stop this obsessive game.Believe me; I'm not interested in playing.

Thanks!

Nathan Cohen, Ph.D.

4104. Impedance of 2 dipoles-1 feedline

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-14 03:52:23 UTC
From: k5fni@my-deja.com
Message-ID: <919g5l$t52$1@nnrp1.deja.com>
Source record: 174704

I'm in a quandary. I got EZNEC and thought it would help me solve my problem. It did not. My situation is two dipoles off one feedline. The longer dipole must work on its quarter-wave frequency and the third harmonic of that. The shorter dipole (not related to the other two frequencies) is along for the ride on the same coax feedline.

Using EZNEC showed me that the ICOM gear feeding these antennas will cut the power back on all frequencies but the shorter dipole's, since with 50 ohms, the SWR will be above 2:1. Am I missing something here? I thought I'd known of folks doing this same trick in earlier days. Maybe they got by with it due to having either a tube transmitter with good matching network or a solid-state transmitter with an antenna tuner. I am constrained from doing any tuning with this antenna. [This is a back-up antenna for an emergency installation. The "long-wire" antenna will have an electronic tuner on it to tune to the necessary frequencies. My design will be the fall-back, assuming lightning or mechanical failure will remove the "long-wire" antenna from service. Another assumption is that the operator cannot operate a normal HF tuner.]

For my calculations, I've assumed the ends of the longer dipole are up 30' and the center is 25' high.

TNX for any ideas you feed back. Replies can be sent to K5FNI at the ARRL dot NET address.

> addition, at no time was I aware that our conversation was being recorded.

If the other person, who taped the conversation, is also in
Massachusetts, then Massachusetts law will apply. If he was in
another state, then that state's laws apply.

If you call me and I decide to tape the conversation, then there is
no need for me to tell you about it. The law in my state says that
if one party to the conversation agrees to its being taped, then
there is no need to notify the other party, and it is legal. If I
tape the conversation, then the presumption is that I agreed to it.

The Federal law simply establishes that basic requirement,-- that one
party agree, and leaves the states free to enact stricter laws.

As to privacy, if you called him, then it is you who have violated
his privacy.

> I will persecute to the fullest should you actually have in your possession

Sorry, Mother Nature disagrees. A good rule of thumb is that a dipole should be at least 3/8WL on its lowest frequency of operation. Even then, it needs a resonating series section transformer.

for most RF filter types, it isn't too much different, so perhaps even
22uH is sufficient, or use a 1/4w reistor with so many turns you can
wind on it using the thinnest wire you can find..

4113. High gain factors calculated for a dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-14 06:59:56 UTC
From: pa2ion@my-deja.com
Message-ID: <919r5b$52s$1@nnrp1.deja.com>
Source record: 174712

High gain factors calculated for a dipole

L.s.

Using NEC as a tool to make predictions of the electromagnetic fields from a 15 m band dipole at varying altidudes some high gain results were obtained at some situations.

NEC-2 from Nittany Scientific calculates up to 14.9 db gain in downward directions (abt. -170 deg) when taking soil conditions with low conductivity and low permittivity and an antenne height of 18 meter. In my understanding a dipole (gain of 2.17 db in free space) has a max. gain of 8.2 db at 100 procent ground reflection. I am still looking for an explanation for this phenomena.

Questions:
1) Are the results right? If so, are those results valid for WORSTCASE calculations at a particular point in the neighborhood of the antenne site (by far-field calculation)?
2) The model output gives also info abt. the near electric field and the near magnetic field: are those values a good estimation of the reality?
3) If both radiation pattern and the near EM-fields are right: can i use those data as a source for an estimation of the bandwith of the EM-field values?

Model parameters:

Now the conservatives can fill the FCC with people that will oppose the ARRL and work to improve amateur radio and license requirements. If the ARRL really cared about amateur radio they would have done so by sending monthly petitions to the FCC proposing ways to improve the service, but it can be clearly seen that the ARRL doesn't care. They want ham radio to be like CB and hams to be like CBer's... crude, stupid and waiting for their next free ham radio license handout.

Most people will tell you there is NO problem with this practice
and others will tell you there IS a problem.

I live about 1,500 feet from a high-rise apartment building (20 floors)
and they have about 40-50 antennas on the roof that are being used
by two-way radio companies, paging companies and cellular companies.

Is it dangerous? I believe a paging transmitter (200-300 watts@900mhz)
could be harmful for those living on the tops floors, but the
owners are more interested in making ($$$) money. We will never
know the effects of these antennas for many years.

4118. Re: am tower question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-14 08:28:14 UTC
From: Gray Frierson Haertig <gfh@haertig.com>
Message-ID: <3A38849F.7CB9167B@haertig.com>
Source record: 174717

Hey Carl,

It is not uncommon to mount other antennas on a series fed AM radiator. There is generally not a problem with intermodulation or receiver desensitization because of the wide frequency separation. The challenge is to bring the antenna coax over the base insulator of the tower. There is a substantial RF voltage at this point and shorting it out causes the AM to not work any more.

There are three common methods for handling this problem. The first is to use a device called an isocoupler. It is essentially a tuned transformer operating at the frequency on the coax. There is a large physical separation between the primary and secondary which presents a minimum shunt capacitance to the AM. The isocoupler has a coax connector on the top and on the bottom. Depending on design it can be mounted to the tower or on and adjacent frame. The top haf of the isocoupler is securely bonded to the tower with copper strap, and the bottom half of the isocoupler is bonded to ground. In all cases, the ground side of the antenna should be well bonded to the tower. The coax should be bonded to the tower approximately every 20 feet.

Using isocouplers can be expensive if there are a quite a few coaxes to be brought across the base insulator. Kintronic Labs is a good source for well made and designed isocouplers.

The second method to solve this problem is to run the coax up the inside of the tower, stood off on insulators. Where the coax crosses the base insulator, the outer conductor is well bonded to the ground system. At a point that is 1/4 wavelength up the tower (at the AM frequency) the coax outer conductor is bonded to the tower and every 20 feet thereafter. Standard coax hangers are used above the short point. This forms a 1/4 wave stub, so the short circuit at the base of the tower appears as an open circuit where the coax bonds to the tower. Again the antenna should be well bonded to the tower. Obviously this will only work on towers over 1/4 wavelength tall.

The third method is to turn the AM radiator into a skirted radiator. 3 to 6 wires are run down parallel to and symmetrically around the tower and spaced away from the tower on fiberglass insulators anywhere from 3 to 6 feet. These wires are bonded together near the top with a circle of wire and the circle is bonded to the tower in 3 or more places. They are also bonded together with a circle at the bottom of the skirts. 3 or more grounding straps are connected between the bottom of the tower and ground, thus effectively removing the insulator from the circuit. The feed from the antenna tuning unit (ATU) of the AM is disconnected from the tower and connected to the bottom of the skirts. This may

require some redesign of the ATU.

In all these cases the ATU will have to be retuned and there some measurements that the FCC requires to be made. In addition a form has to be filed with the FCC indicating what the new base impedance of the tower is and hence the proper base current.

There are a number of trade-offs, depending on the electrical height of the tower, the number of coaxes needing to go across the base, and what the potential for future expansion is. If you are not familiar with AM practice, measurement and tuning, you should hire an engineering consultant to help you through the process of deciding which technique to use, to design the the system and to make the required measurements and adjustments after the antennas are installed.

If you wish to discuss your project with me, please feel free to contact me off list or call me at the office. These are the kind of services my firm offers.

There was a big protest here in New York because Sprint signed a
contract with the local school district to put an antenna on top
of a flagpole at the local high school. People only found out
about it after the contract was signed and there were all sorts
of protests, they went to the state education commissioner, but
were unable to get it voided.

What I find amusing is that many of the people who protested
this likely complain to their cellular company about poor
coverage, and many of the high school kids who are protesting
probably put cellular phones up to their heads every day.

I'm sure you could get the exact specs from Force 12. Off the top of my head, the C3SS has a shorter boom and shortened elements. The C3S is full-sized and I believe was actually the first design in the C3 series. If you have the room, go for the C3S.

The C3S performs on a par with the C3 - did an extensive on-air comparison test and confirmed this myself.

Source record: 174826

Dear all,

The various responses to my question have been quite interesting. But only one response was from someone who had had practical experience and he reported no unusual problems encountered in using the network. Perhaps one conclusion I could draw is that Pi-L networks are very few and far between.

Ordinary circuit analysis programs provide no guidance on what happens during a minimum-dip tune-up procedure. They merely demonstrate the existence of double humps in the input impedance versus frequency curve, the spacing and lack of symmetry of which depend on circuit Q. Someone has pointed out that, in general, a pair of humps is deducible from the numbers of coils and capacitors. From an impedance matching aspect one C and one L are redundent.

But when tuning up the frequency is not a variable. - it is the two capacitors which vary. What I would like to know is to where on the input Z/f response does the tuning up procedure lead ?

And are the two capacitors used in exactly the same manner as the "Load" and "Tune" capacitors in an ordinary Pi-match network ?

>done.
>

I put an A 99 up here as a joke @ 7 ft off the ground and ran 4 6 guage 8 ft 4 in radials that I clamped to the gounding section of the antenna with a pipe clamp. The antenna worked as well or better in some cases on DX then my Anttron 305 with no radials @ 47 ft on top of the tower. also found that I could work 17 and 12 mtrs as well bypassed on the tuner with this antenna. There are a couple of very good ground mount lifts that you could purchase. These fold over and lay a verticle down. look up Alphs Delta DH 1 or DH 2 on the hamradio.com web site, or in your HRO catalog(ordered from above web site). Good luck on the upcoming tests and hope to hear you al others reading this soon on the 10 meter Wacky Wingding net on 28.390 Monday nights @ 7:30 EST. 73 and Happy Holidays de KG4FET Sandor

What??!!?? I doubt it. I really doubt it.

The radar gun has a trigger that turns the emitter on and off. When a police officer wants to check your speed, he points the gun at your vehicle and pulls the trigger -- just like hitting the PTT switch on a handheld. The radar gun is not emitting any signal when the trigger is not pulled.

I doubt that police offices sit around with the radar gun in their laps with the trigger pulled. The ones I have seen have the gun mounted in a "holster" on the dash or lying on the dash when not in use.

Please cite a documented medical source for this claim -- not some urban legend and certainly not Art Bell.

Chuck O'Neal has defined his own agenda and it is a full one. Now please be quiet and let him pursue it--and let his attorney advise his client to stop harassing and libeling the very person he wants to sue. Or let him stop harassing me. Period.

Either way we all win, as we return to a nice, quiet NG and no mendacious claims of small beams with 6 dBd gain.

Actually some of the older models blasted all the time. You had stupid cops who would take units made to be mounted permanently to the vehicle and put them in their lap. Those devices were cheaper to buy than the ones with the triggers. It took 20 years of doing this to develop tumors.

From what I understand the radar guns give off substantial energy, you can pick up a cop for miles and miles with a radar detector, but the stores which use X band radar for automatic door openers are only picked up for a few thousand feet when you're driving down the road. Also knowing that radar is 45 GHz and a bit about radio propagation, they do appear to be high power devices compared to cellular towers that operate at a much lower frequency in a band with considerably less free space loss.

Right you are Mike. The induction fields can be be strong
(concentated) and radiation poor, but there will always be radiation.

>What??!!?? I doubt it. I really doubt it.

Some people really are foolish. They will suck up any urban lmyth and
pass it on as a fact.

The only link ever found between non-ionizing radiation and cell
damage turned out to be falsified. The "scientist" who did the study
was fired from the school he worked at, and the data in the study
dismissed as false.

Because of that one single false study we now will have years and
years of urban myth talking about dangers of non-ionizing radiation.

Bottom line is if the EM radiation from power lines or radio signals
is not strong enough to elevate your cell's temperature, it will do no
harm no matter how long you are exposed to it. There has never,
despite some of the most extensive tests ever made, been any link
between this type of EM radiation and damage to animals unless the
field gets so intense it cooks them.

You know the stories about the cops is pure unvarnished bullcrap
because the guns are off unless the cop is checking the speed of his
crotch, and the damage is not accumulated over time.

An antenna on any band will work at very high efficiency
(>90%) when 3/8ths or more wavelengths above any sort of
ground. For the 6 metre band that's anywhere above 8 feet.
And even as low as 5 feet you will get around very well.

What REALLY matters is height above obstructions in the
immediate vicinity. A satisfactory height in New York City
is 8 feet above the Empire State Building. But at the
bottom of the Colorado Canyon you have REAL problems.

Chuck- I note that Chips attack has changed since it has been pointed out that recording is OK, if one party aggrees.- However- I have one quibble- with regard to his"reputation".
His reputation is intact, but it is highly negative. His current approach is only enhancing his reputation, which resembles that of "a junk-yard dog".

Stick in there- I hope this helps.

A vertical ground plane antenna of aluminum tubing worked fine at 15
feet with 5 watts. You don't need much when 6 meters is open.

Chuck, I've heard this so many times on this NG--especially from you-- I must confess that I wonder if credibility is like a gas tank where you say 'fill'er up'. How else could I have any left--according to you:-)? The fact is that you have called me a homosexual ; fool; and sundry other libelous things. The fact is that you have illegally--by your own admission--wiretapped a phone conversation we had . The fact is that you claim that my signal is a factor of--1000-- down from yours (yet it looks like I came in second in the country in my class on the recent 10M contest). The fact is that you now claim a 6 dBd small yagi that beats the FQY. Among other things.

My 'attack'--to use your incorrect characterization --is an expression of the truth, to counterbalance the lies and distortions you introduce.

>Your attack on me was unjustified! What is left
>of your reputation is on the line here.
>Do the right thing.
>

Chuck--

If you are going to sue me then please get on with it.

If you are going to post a wav file from an illegal wiretap then please get on with it.

If you are going to notify the "appropriate individuals" then please get on with it. Be sure to tell them you are party to a lawsuit against me.

If you are going to drive me into insolvency then please get on with it.

All these--and more --you claim to be doing. So just do it. Or be quiet.

It is a switch Chuck. Either be truthful and nice-- or be litigious and quiet. Either way the NG wins and I won't have you harrassing me anymore.

As to my response, I think you would have done well to measure and understand WHY the NG has been so quiet lately--until you decided to rant things up.

Do you want an apology? OK: show us published data on your 6 dBd small Yagi and I will not only 'apologize' but I will remove the 10M FQY from the web.

Do the right thing.

Cordially,

Nathan Cohen, Ph.D.

Reinforced concrete makes an excellent shield. Also, the
signals decrease in strength with the square of distance.
i.e. when you move twice as far from the antenna, the signal
strength is reduced to 1/4. In addition, I doubt the antenna
patterns would be configured to send the power straight
down.

Before he quit this past year, Art Bell was a nationally syndicated radio announcer, broadcasting out of his home in Nevada, who had a 4 hour night show, on the paranormal, Nostradamus predictions, alien and government conspiracies, etc. Think of him like a rabid Fox Muldar, and that describes Art Bell. He's been replaced by someone else for the broadcasts, but if this kinda stuff still interests you, there is a website, IIRC - www.artbell.com
.

Exactly right. Some folks realize this is true only because the 6 metre band is usually not propagated by the ionosphere as it is above the maximum usable frequency. Others may miss the point that 50 MHz is usually only good for line-of-sight paths.

For ionospheric propagation, 1/2-wave antenna elevation is enough. For line-of-sight, the elevation needed is whatever it takes.

I spent a week rafting down the Grand Canyon. Medium wave reception was near zero. Shortwave reception at the bottom of the canyon was actually very good.

Best regards, Richard Harrison, KB5WZI

Reg,

I would think that Pi-L networks are fairly common, because they are needed to provide enough filtering for amplifiers to meet the FCC's requirement for spurious emissions. I don't say this from experience, because I don't own a power amp, but if you do the math, I think you'll find that a Pi network alone won't do the job, particularly if coupled to a multi-band antenna that provides a good response at a harmonic of the frequency in use.

4150. Epiphany on the T2FD (or B&W folded dipole)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-14 16:13:39 UTC
From: munsch@attglobal.net
Message-ID: <3a39a456_3@news1.prserv.net>
Source record: 174660

Group:
I ran across an old Army manual which discussed the T2FD, and one of the points made may explain some of the divergence of opinion on here concerning the B&W version so frequently asked about. The manual recommended against horizontal mounting, but indicated that more nearly omni directional coverage was obtained by having one end much higher than the other(sloper, I guess). While the antenna is not real efficient at the low end, it is wide band, and for the military or other users which require frequency agility way beyond a half-dozen ham bands, it fits the bill.
Crazy George

Well, if you live 1,500 feet from the antennas, you are exposed to 10,000 time less energy that someone standing 15 feet from the same antennas, and 2.5 million times less than someone standing 1 foot from the antennas. This is based on the distance-squared law that all radiating signals abide by in open space. Your risks from the site are so marginal that you probably stand a higher risk of being hit by a crashing 747 with Stephen Hawkings onboard.

My Force 12 catalog shows only a C3 and a C3S (Special) where the C3 is
rated to survive 80 MPH winds and the "S" 100 MPH winds

The catalog indicates that versions capable of 120 and >140 are available.
From the data I would suspect that it is a 120 MPH version.

Aw, comeon CC... the Isotron has a tuned circuit. I fact that's all it
is- a larger scale tuned circuit, up in the air. I suspect an
oldfashioned plate tank circuit mounted where your antenna feedpoint is
would radiate as well.

Sure they'll work. You might get a bit of a skewed pattern but so what?
Hams use all sorts of schemes that they find in their surroundings for
antenna systems, metal fences, small diameter wires hidden in the grass,
cracks between grass and sidwalk, you get the drift. Just run a wire
from the radial wire feed to the antenna and hook it to the coax shield
at the vertical feedpoint. Of course that wire will also be a part of
the radial system but it WILL work.

You'd be amazed at how many hams in past years have just driven a
ground rod at the spot where the vertical antenna was mounted, and
hooked to it for the counterpoise. In fact many vendors have asserted
that was all that was needed, and in fact it usually worked very well,
if you base that evaluation on contacts made on the air.
Your unusual radial system is certain to work better than a ground rod
alone.

Maybe, maybe not. From http://www.amsat.org/amsat/news/ans.html

"Early Wednesday, December 13th, telemetry transmissions from AO-40
stopped while work on the 400 N propulsion system was in progress. An
investigation by the AO-40 development team has begun. They are now
waiting for certain on-board software events to occur on Saturday
afternoon, December 16th. These are programmed to start a spacecraft
emergency routine called 'command-assist' which attempts to re-establish
communications. This offers the best chance of recovering evidence of
the incident which made the telemetry transmissions stop."

I agree that Carl Westerman`s 1850 MHz cellular coax would be better decoupled at one MHz, more or less, by using an isocoupler than by making a 2 millihenry coil of coax. Small coax would be too lossy and large coax would take too much space.

Best regards, Richard Harrison, KB5WZI

I am working on a project to set the Solar powered radio controlled model altitude record. My airframe should be good for > 30K ft and I need to make sure that my radio liks will operate reliably to that altitude.

My page of notes pictures electronics notes etc...:
(Not well organized)
http://www.rasdoc.com/splinter/

The FCC regs limit me to 1W maximum output on the uplink.
At the present time the downlink is a 900Mhz 1/2W video transmitter.

I am looking for an antenna guru to help me design the needed antennas.

For the 900 Mhz downlink I am using a commercial loop yagi for the RX and need to develop a transmitter antenna with a hemispherical pattern for the plane.

My current plans are for a homebuilt 1W 6M uplink, then using a normal RC receiver on the aircraft.

My current thought on this is as follows:

On the ground use a simple 1/4 wave steerable rigid dipole.
This might be upgraded to a 2 or three element YAGI if I need the gain.

On the plane I was goint to use a pair of 1/4 wave dipole's at 90 degrees to each other, how can I combine these to provide a full hemisphere of coverage?

"For most filter types, it isn`t too much different, so perhaps even 22 microhenries is sufficient, or use a 1/4-watt resistor with so many turns as you can wind on it using the thinnest wire you can find."

Mr. Noedling is probably exactly right. For grins, my ARRL coil calculator says single-layer 1-mhy coil could be wound with No. 22 wire at 37 turns per inch. If you have a 4-inch diameter, you need a winding length of about 3 inches. If you have a 2-inch diameter, you need a length of about 8 inches for your 1-mhy coil.

All too true, because in science you can never prove anything 100%. People like that therefore seize on the "potential" hazard, even if all available evidence cannot actually prove a measurable hazard.

Get a Comet SBB5 dual band antenna in either pl-259 or mno mount. It is a fold over antenna with only an air coil half way up. Very rugged antenna. 2m is 2.15dBi and 446 is 5.5dBi. 39" high. Max power 120w. I have had one on top of a pick up and/or Suburban for several years and it has held up well. Using it with either a MKII or a MKIIG. If you really want a lot of gain, but are willing to sacrifice ruggedness and deal with a higher antenna, get the Comet Z780. 62" high. 150w. fold over. 2m is 4.5dBi and 446 is 7.2dbi. Average mag mounts will NOT hold this antenna at highway speeds.

No.

All that is known is that AO-40 abruptly went off the air during ground station operations. AMSAT have confirmed this. There was an anomaly with the 400N thruster firing. Again, AMSAT have confirmed this.

Exactly what has happened is not yet known, so it is inappropriate to declare the satellite lost.

There are several levels of recovery, and the controllers are working on them. Let them do so.

Source record: 174629

It is easy to check a trap. Connect one side of a grid dip coil to the inboard end of the trap with a small capacitor, 2 to 5 pf. A good trap will give a pronounced dip at its resonant frequency. Some traps seem to be set for the low end of the band to reject, others at band center. I havn't found any difference in performance.

If ypu want to try shrink tubing, check the trap before and after. If there is a change in frequency or dip depth, the material shouldn't be used.

I have covered very old traps with clear epoxy, and used them for years.

A trap with a poor dip can SOMETIMES be restored by placing it in an oven at 150 degrees for a time. Don't get them really hot- they might melt the coil form.

Thanks Tom,
Yes, my concern is that if I replace the tower leg with a vertical wire, or even a gang of vertical wires, the bandwidth will be reduced...greatly. This Wermager antenna is a bit different from a sloper in that the main element is almost like a vee-beam, and the shield-fed element is like an inverted-vee with a vertical leg (usually the tower)....but it's omni. Anyway, maybe I'll play around with the thing a report back here what I find. Thanks again for the input.

This is factually incorrect. Two officers in one state contracted
testicular cancer. No other officers anywhere else contracted testicular
cancer, at least that could be attributed to a radar gun. Seems like the
exception that proves the rule.

Don't worry about it. The FCC has stringent regulations concerning acceptable exposure to RF radiation. The guidlines apply to all tenants occupying a common site. Therefore the total radiation emitted from all of the transmitters must not exceed the specification.

4195. UPDATE: Chuck O'Neal lawsuit Against Nathan Cohen

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-15 01:07:49 UTC
From: fractenna@aol.com
Message-ID: <20001214200749.28473.00005015@ng-cr1.aol.com>
Source record: 174641

12/14/00

These info pieces will be posted from time to time to keep others up to date.

Mr. O'Neal has yet to take measureable action against Dr. Cohen, despite his claimed pending lawsuit.

In related news, Mr. O'Neal has not made available a .wav file which he claimed he would post. This file alleges to contain material revealing that Dr.Cohen has prevaricated and fabricated material relevant to a conversation he had by phone with Mr. O'Neal in 1998. Dr. Cohen was not aware of the recording of any conversations he has had with anyone, and did not give permission for any recording.

Dr. Cohen has consulted a Boston attorney in the event that wiretapping charges need to be brought against Mr. O'Neal. Dr. Cohen reviewed the Massachusetts Wiretap law and was advised on its implications and seriousness of transgression. Dr. Cohen was also asked to summarize multiple post transmissions by Mr. O'Neal on USENET which targeted Dr. Cohen with statements of malicious libel ny Mr. O'Neal. Such statements are publicly archived and available worldwide.

Separately, Dr. Cohen is now reviewing whether to bring suit against Mr. O'Neal for malicious libel and other charges. Such charges, if pursued, will be brought up in Midddlesex County, Massachusetts.

To give the devil his due, the darn things WILL radiate. I tried one on
75 meters and worked about 200 miles on it with a copyable signal, and I
had not been able to get it resonated to my satisfaction so used the
rigs internal autotuner @100 watts. They are like any normal resonant
tuned circuit, pretty darn narrowbanded. Of course the 160meter version
will just be that much less efficient.

Hey fracky, I know you just can't wait to get sued in this age of instant
gratification...but you are just going to have to wait. It appears that I
will
add to my claims given the results of today's preliminary investigation.
We estimate another three (3) weeks before all claims are properly defined.
This does not include two individuals that have come forward with
additional relevant information. We also need to plan for the Discovery
phase.

Why don't you just post your address so you can get all sorts of people to 'aid' you in your cause?

Here it is: available from http://ww.qrz.com publicly:

CHARLES D. O NEAL, III
PO BOX 369
BOLTON MA 01740
USA

I think one should also take this opportunity to more widely disseminate your ongoing suit so that it gets maximum coverage within the radio amateur community and elsewhere . That's what you want , isn't it? I mean, that's why you put this on a public forum with global and archived ability, isn't it?

>>In related news, Mr. O'Neal has not made available a .wav file which he

>Be advised that all your postings are available too!
>Show them to your lawyer and see if he still will
>represent you!
>

Again, your comments do not seem to indicate a knowledge of lawsuit law. Mine is rudimentary but under the advice of counsel.

If yours was under legal counsel, it certainly would not suggest that the party you claim to be suing, had so prejudiced his case that legal representation was not possible. That is exactly what you have just said--twice. Your insinuation is that the party you are suing should not be represented by the legal system.

One must further remember that you have clearly stated that your intent for said suit is to bring financial ruin upon me; not as a settlement against alleged grievance, but purely to destroy me financually. In other words, that was ALWAYS your intent, and any 'grievance' is just a ruse for that plan.

I presume this will now be run past a judge.

Cordially,

NC

Up where I am (suburban NYC), all companies have spots where they have poor coverage because they have trouble getting approval to put up more towers. I'm sure that people complain about this all the time, and I don't think it's unreasonable to think that some of them are the same ones protesting this new tower, which would improve their signal.

Bill

4218. Re: am tower question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-15 07:38:13 UTC
From: Gray Frierson Haertig <gfh@haertig.com>
Message-ID: <3A39CA65.7B58B97C@haertig.com>
Source record: 174666

Richard brings up a fourth method commonly used to solve this problem
that I neglected to mention in my other post - and that is an isocoil.

This is large inductor (typically 150 uH or so) wound out of whatever
coax one desires, though in most applications at the relatively low
powers found in PCS service, 3/8", 1/2" or 5/8" foam heliax is used.
The the amount of cable incorporated in the inductor doesn't constitute
a great loss. If there is more than one coax to bring across the base,
the inductor can be wound in a multifilar fashion using multiple coaxes.
These coils are on the order of 1.5' to 2' in diameter and about 3' to
3.5 feet long. It would go inside its own weatherproof enclosure
adjacent to the tower. The outer conductor of the bottom end of the
coil is bonded to ground, and the outer of the upper end is bonded to
the tower. The coaxes are usually wire tied to the feed pipe going out
to the tower. There is a type N or UHF connector(s) for the input and
output. The connector(s) on the tower side are usually mounted in an
insulating window.

If the base impedance of the tower is very high, the isocoil can be
parallel resonated with a vacuum cap so that it presents a very high
impedance to the base of the tower.

This is probably the least expensive way to bring several coaxes (6 or
so) across the base insulator.

Kintronic Labs makes these. Their work is very high quality. The can
also provide the enclosure and, if necessary, the vacuum cap, pretuned
at the factory.

You would still need to have a consultant come in and measure the base
impedance of the tower after installation.

Thanks for jogging my memory, Richard.

A trap with its capacitor can also be checked far more
accurately than by gdo, by using an antenna analyser, Autek
or MFJ.

Just connect a 2-inch diameter loop to the analyser
terminals and hold it near or over one end of the trap.

Vary frequency and search for a very sharp increase in
impedance from zero to perhaps a few hundred ohms.

One thing about looking at parallel dipoles on one coax feed in eznec
etc. When you change bands, you need to change the source. I'm getting
the feeling you may not be doing this. If you don't, you will get some
funny readings. Say you are running a 160,80,40 dipoles one one feed.
Lets say wire 3 is 160, wire 5 is 80, wire 7 is 40 as an example. When
you look at the plot for a certain band you need you set the source to
match the band.
In the real world ,the unused legs will be ignored unless there is
coupling. So I think it's most accurate to look at each band with the
proper source. I bet your data falls more into line with the normal if
you do that.MK

I've been going over the diagram for this henry. If I'm reading this thing right only the #2 L-net cap is variable. Lets say the normal pi-l uses 3 L-nets back to back. In a diagram I'm looking at in the Orr radio handbook, his example uses variables for each cap in each L-net. But my amp is not set up that way. On mine, the first L-net in the line uses fixed caps which are set by the bandswitch. This amp uses a roller for the inductor. And it is the "tune" control on the amp. The cap in the "2nd" L-net is the variable in this case. It is the "load" control. On the 3rd L-net, again the caps are fixed and set by the bandswitch. Also the 3rd inductor in the pi-l is also tapped by the switch according to band. So in this case, the only cap that is variable is the "2nd" L-net cap. And it is the load control. This connects to the inductor tap which is the "tune" control. The first and third caps in the network are fixed

and selected by the bandswitch. Hopefully, this makes some kind of sense...I could make a copy of this circuit if it would help to see it. Also I notice in this book, Orr, sez a formal calculation of the pi-L circuit parameters are given in the article "The pi-L plate circuit in Kilowatt amplifiers" QST, july 62. It's says a free reprint of the article may be had by writing to the amatuer service dept. of EIMAC. You might ask around on the amp reflector. They could probably give you more info. Also, if anyone notices a mistake in my description of the henry circuit, chime in. It's still early for me yet, and my brain is only at half speed. I haven't yet finished my first cup of mud, so the caffeine hasn't kicked in yet. MK

One reason why I like the lower hf bands when camping. You have the same problem even in the fairly shallow river bottoms here in TX. I kayak on a few of them in the hill country. Being I'm usually on 80/40 meters and working regional, it doesn't hurt me much at all. But try to tune a local 2m repeater? Might as well hang it up, or get in the car and drive up the hill to get out of the "rut". But I string low dipoles up that aren't ten ft off the ground and I'm below grade 80 ft, and still do fine on 80/40. Even the higher hf bands will work ok usually. Ten meters would see a big cut if working local or dx though. MK

Actually, it's a common problem. A while ago, I read an
article about cell phones, and someone from one of the
Canadian cell companies said there are people who want to
use cell phones, so long as the base antenna is not near
them. Something about property values. ;-)

Gray Frierson Haertig wrote:
"If the base impedance of the tower is very high, the isocoil can be parallel resonated with a vacuum capacitor so that it presents a very high impedance at the base of the tower."

Yes. This is a sensible solution. A high impedance with few turns can be obtained using parallel resonance. Often at h-f, coiled coax chokes are made approximately self resonant. At AM broadcast frequencies, this would take many turns.

As usually only one frequency is involved (my first broadcasting job was at KPRC, 950 KHz / KXYZ, 1320 KHz, which shared a common tower at the time) tuning is simple and doesn`t often need resetting.

Few enough turns to avoid excessive loss at the cell phone frequencies in the coax can be used by resonating them at the AM broadcast frequency with a vacuum variable capacitor. If the voltage isn`t too high due to power and base impedance, an ordinary air-dielectric capacitor may be adequate.

Best regards, Richard Harrison, KB5WZI

In New Jersey, I've suspected that this is the reason cell phone signals are so terribly weak around Princeton, a town chock full of very rich people. The last couple of times I was in Princeton on the University campus, the phone was all but unusable.

4234. Re: MFJ antenna analyzer, NG on Diamond ant.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-15 14:16:07 UTC
From: n1kk@my-deja.com
Message-ID: <91d934$so3$1@nnrp1.deja.com>
Source record: 174584

When using the MFJ antenna anlyzer on the Diamond V2000A the 2 meter
resonance was around 155MHz and the 6 meter had 2 dips (49MHz and 55MHz)
Before I had a chance to describe this to the people at Diamond they
told me with the MFJ analyzer they noticed some of there antennas show
a higher resonant frequency. The Bird 43 measured the resonance
on 6 meters favoring the FM section of 6 meters. This is where I
adjusted the tuning based on their chart. The built in SWR on my
IC-746 backed the bird 43 measurements.
On 2 meters the bird 43 measured resonance in the middle of the band.
I used my IC-706 for 440 and with the bird it was fine. My MFJ 259
does not cover 440MHz

You've invented a scenario intended to discredit those who protest
the site. IMO it's unlikely anyone who actually complained to the
cellular company about poor coverage would also protest a new cell site.

Not everyone benefits from cell phones. People have a right to try
to limit their exposure to unreasonable or unnecessary levels of
radiation. Safety standards change. What is considered safe today
might be considered unsafe tomorrow. Ask asbestos workers.

I looked up a website about a Sprint PCS hearing for placing a site
on a school's water tower. The exposure numbers involved there were:
PCS sites transmit up to 100 Watts.
The Federal exposure limit was quoted as 1.1 milliWatt/sq cm
The Sprint PCS exposure to kids was estimated to be 0.08 milliWatt/sq cm

For what it's worth, that PCS level is above the official Russian safety
standard. As I recall, the safety standard in the former USSR was
-20 dBm/sq cm or .01 milliWatt/ sq cm. Is the US standard too loose,
or is the Russian standard too tight? --I don't know. Do you?

OK:

"Hello Asbestos workers. Can you name one detriment caused by cell phones.?"

I shall suppose that we will now see this NG degrade to pseudo-biometry and the pernicious misinterpretations it engenders.

The fact is that not ONE health or social problem is CAUSED or AGGRAVATED by cell phones.

Not ONE.

Keep the pseudoscience off this NG please.

His "invented scenario" pales compared to the bolognia heap of the
paranoid people who quote folklore and half-truths as fact.

IMO, it seems quite reasonable to assume some of the overly paranoid
about exposure also want better coverage. That happens here in my
county, where some of the people I saw show up at a meeting to protest
a new tower were the same people who bitched personally to me about
how poor their phones work around here.

>Not everyone benefits from cell phones. People have a right to try
>to limit their exposure to unreasonable or unnecessary levels of

This is probably one of the most investigated things in studies that
we have ever had. I personally know someone who has been looking at
effects of EM radiation in a lab for at least 20 years for medical
research! He, and everyone else I know of in the field (and I know
many people), all say over and over again if the temperature of the
cells aren't raised there is no effect on the cells.

He told me the ONLY study linking EM radiation to cancer was falsified
a year or two before the government finally concluded it was faked.
While the correction made it on national TV, it was a short blurb. All
the paranoid people inventing stories or repeating false rumors get
all the press.

It is the Chicken-Little syndrome.

Please tell me where I can look that alleged "Russian Standard" up Don. Even the US standard is extremely safe. The damage concern is COOKING, not cell mutation. It takes an ionizing form of radition to cause accumulated damage, not a lower frequency (radio spectrum or lower) form.

That's what I use on my 300 foot tower to get the higher frequency
feedlines past the base insulator.

Ken and all,

It amazes me the antenna manufacturers seem to not understand how an analyzer works.

Let's assume the analyzer is functioning properly as shipped, and you do not have a very strong local source of RF screwing up the analyzer's detetectors (which will cause a high SWR reading everywhere).

If the analyzer is showing a different resonant frequency, it can ONLY be because the antenna has a design flaw such as a lack of perfect feedpoint unbalance.

I know that balance flaws are very very common with VHF antennas because many manufacturers use an inadequate groundplane or decoupling at the antenna base. This allows common mode currents to spill over onto the feedline shield.

Depending on how and where that shield is grounded, the SWR will vary. At times when the feedline is grounded by the physically large radio and everything connected to it, common mode current becomes less noticable. An analyzer, especially with a short feedline attached to the antenna, presents little or no termination to these unwanted currents. They may show as a high SWR (because they are are actually causing a high SWR).

It's a common excuse, when the antenna has a design shortfall, to blame the test equipment. But if the antenna analyzer is NOT DEFECTIVE, and measures test loads correctly, it will measure an antenna correctly.

Claiming otherwise is a clear demonstartion they simly don't have any idea what they are talking about.

Jason Hsu, AG4DG wrote:
"No, I don`t expect to win contests, bust pile-ups, or earn my WAS with lightning speed."

Shortened radials can be effective say some experts. Some say total wire used for h-f radials can be the same in either twice the number of 1/8-wave radials as would be used in 1/4-wave radials, or in the 1/4-wave radials themselves, with almost the same results.

This may be the wrong question for short hop communications. The U.S. Army made tests at 3 MHz over a 75-mile path in South Florida where soil conductivity was excellent. Using a 15-foot whip on each end, and excellent ground connections, produced a 38 db weaker signal than 1/2-wave dipoles at each end when these dipoles were only suspended at 7 feet above the ground.

Raising the dipoles to 30 feet above ground at each end improved the received signals by another 21 db at each end of the path. For an unexplained reason, the army increased the path length to 150 miles for the 30 foot dipole elevation tests. As the radiation is about the same for either elevation angle for the different path lengths, the same gain would be expected at 75 miles path length.

The point is that the 1/2-wave dipole is a much better antenna for short distance sky wave communications than is a resonant loaded short whip, even when the dipole is only 7 feet off the ground and and the whip is 15 feet tall. 38 db better for two similar antennas at each end of the path!

Best regards, Richard Harrison, KB5WZI

Well, one social problem is people like to talk when driving. Some
people don't do two things at once well. So that kind of blows your not
ONE in the social dept.
>
> Keep the pseudoscience off this NG please.

Boy, you are one to talk about NG content. Maybe he will make a deal
with you. If you help keep the whiny lawyer crap off the NG , maybe they
will keep the pseudoscience off also. Sounds like a fair deal to me. But
actually I don't consider what they said as pseudoscience. Maybe undo
paranoia, but not pseudoscience. Can you prove that there are no long
term effects of cell phone radiation to the head? Being as they haven't
been around too awful long, I don't see how you could. And people do
have the right to limit their exposure to this rf is they so choose. So
I'd say he has a leg up on you in the NG content dept compared to other
posts I see recently. Pot+kettle=black MK

I remember reading the Russian standards back in the 70's and 80's
in IEEE Spectrum magazine when I was involved with microwave
transmitter design.

I found a web reference to the Russian standard in the IEEE Antennas
and Propagation magazine at

http://www.eecs.uic.edu/eecspeople/lin_ieee4.htm
It says:
Indeed, it has been known for years that the RF guidelines promulgated
for limiting human exposure vary from country to country. For example,
according to the Sanitary Regulations and Standards 2.2.4/2.1.8.055-96,
"Radiofrequency Electromagnetic Radiation under Occupational and Living
Conditions," the permissible exposure level for the general population
in the Russian Federation is 10 ï¿½W/cm2 or 0.1 W/m2 in the 300 MHz to
300 GHz frequency range [3]. The American National Standards Institute
(ANSI) guidelines for the same frequency range are 1 to 10 mW/cm2 or
10 to 100 W/m2, depending on frequency [4].

Note that 10 uW/cm2 is .01 milliWatt/sq cm.

Tom is correct. When you change your instrumentation configuration, you are also changing the antenna *system* that you are measuring. Without good common mode current reduction (typical in a "ground plane" antenna) the outside of the cable is part of the antenna. As you fiddle with its length, you change the system resonances.

Having been spoiled by having access to high quality netwrk analyzers, I'm no big fan of some of the hand-held instruments offered to the ham community, mostly because they promise more accuracy than they can deliver. Nevertheless, in this case I wouldn't fault the instrument.

For the moment I will forgive your personal content and concentrate on the other statements.

Cell phones do not cause car accidents. Distracted people (among other causes) produce such accidents. If you are distracted by ANYTHING--be it a cell phone or hot Danish in hand--then put it down and drive. If you aren't, then don't.

Locally, there is now a cell phone ordinance when driving. My next question is: should we now also put an ordinance on children; CD players; argumentative passengers; and --or course-- that hot MacDonald's morning coffee? And what about that oh-so-distracting smell of a pepperoni pizza coming back from the local pizza place?

As for the asbestos analogy, it wasn't mine. So don't ascribe it to me. My point is that it WAS irrelevant.

Hi Chip,

The argumentation on topics like this partly relies on statistical
results.
Not one of the people who are running lawsuits agains tobacco companies in
your country can prove that his "personal" lung cancer is a result of
smoking their cigarettes. You can only have a statistical answer. This is
true of almost everything related to medicine. Does that mean that
medicine, biology, partly chemistry etc. are pseudosciences ?
Most of the things around us can be led back to the law of physics, but
given all quantum formulas no one on this planet is able to describe
exactly how a HIV virus enters into a cell or what happens exactly at the
cells membranes. But I think biochemistry is no pseudoscience. For most
medicines nobody knows exactly why they have an effect, anyway the people
working in this field are not pseudoscientists to me.

With only very few exceptions you always measure "bulk quantities", even
in "exact" physics.

I agree that rf radiation will not ionize any DNA molecule and that the
energy absorbed by human bodies and converted to heat should be far from
being critical.

Anyway I do not know if the spatial "shape" of a DNA molecule can be
modified by rf radiation and what effect this might have. I just know that

1. You could not measure it (you just don't have the resolution)

2. The action of medicines depends on the spatial structure of the molecules (Their spatial shape can depend on how you produce them). It is not just the chemical formula that counts.

I would argue that the energy of one 1900 MHz quantum is well below a the thermal energy and that all shapes a DNA molecule could be converted into will also be reached by interaction with the warm environment, meaning no effect of the rf radiation.

The fact that you cannot prove any danger does not mean that this danger does not exist.

I've never seen an electron but I believe they exist.

The usage of cell phones when driving and in restaurants, theatres etc. surely is a social problem.

I believe there is potentially a health danger but I think the coincidence will be to weak to prove it, meaning the physical quantity is "smaller than the error bars" and therefore not measurable. To many other factors will smear out all measurements.

I agree with you that there should be better NG for this kind of topic but I would not call it pseudoscience.

Life as we know it developed without the presence of pulsed coherent rf radiation, but seems to be tolerant against most kinds of "pollution" of its environment.

Distance is always a good mean to keep the risk low. Society will accept a small risk if it sees that unnecessary risks are avoided (there surely is a risk in using nuclear power but it is accepted if unnecessary risks are avoided).

If your government gives upper limits for rf radiation it means there is evidence for a risk. (If rf is not dangerous why should I give upper limits ?)

4260. Re: am tower question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-15 18:22:30 UTC
From: Gray Frierson Haertig <gfh@haertig.com>
Message-ID: <3A3A6165.5B23FCD5@haertig.com>
Source record: 174607

Modern AM construction generally tries to avoid air dielectric variables
(though I have quite a collection taken out of old installations when
rebuilt) because of their tendency to change value when the spiders,
wasps and mice move in. Not to mention the bottom of the enclosure
begins to look like a small animal abattoir.

For towers in the range of 1/4 lambda, which a large majority of AM's
are, the base impedance is low enough that resonating the coil is
usually not necessary. It's usually cheaper to add sufficient turns to
bring the impedance up than to add a vacuum variable.

As I mentioned, the commercial units are typically about 150 uH, which
translates to a bit over 500 ohms at 550 KHz. This is more than a 10 to
1 ratio with the base impedance of a 1/4 lambda tower. At 1600 KHz it
is 1500 ohms. The loss at PCS frequencies is not so great as to be a problem.

And your point is? Are you trying to argue that ANYTHING is possible? If that's the case, then it is also possible that you will contract cancer from signals coming from a transmitter on the opposite of the world. Of course we could argue about how unimaginably weak those signals would be, but you would simply argue that even more improbable things have happened.

So exactly what are you suggesting that we do? Shut down all RF transmitters on the OUTSIDE chance that they MIGHT cause someone to contract cancer?

Yri, K3BU wrote:
"...and that`s why broadcast stations use verticals to get local coverage on AM."

Yes, the AM broadcast station reaches listeners by the ground wave signal. Horizontal antennas see reversed image reflections which produce cancellation of the wave traveling along the earth`s surface.

Vertical grounded antennas produce cancellation at the zenith and maximum radiation along the earth`s surface, at least at the tower heights used for AM broadcasting.

An HF surface wave is attenuated in such a short travel distance along the earth`s surface that it is soon useless. It is absorbed before it can reach the ionosphere for reflection. Only radiation elevated at several degrees above the horizon is useful for ionospheric reflection.

The 3 MHz tests conducted by the U.S. Army depended on ionospheric reflection between path ends. These were "near vertical incidence" tests over path lengths of 75 miles and 150 miles.

Best regards, Richard Harrison, KB5WZI

MMM....stupid people (er to be PC, "uneducated")
....mmmmm....paranoia...mmmm......

Well, for all of you out here who are all paranoid about cell phones...how many of you use 900 MHz cordless phones? You can't use the old skool 49 MHz "25 channel" phones because it's so easy to intercept, so most people these days use 900 MHz digital cordless phones.

A LOT of people use cordless phones, and power levels are a bit different, but not by much. the 800 MHz cellular band might as well just be considered 900 MHz, it's 869-896 MHz, which is pretty close, and anyway, most people think higher frequency means "more radiation."

How many of you are acting hypocritical and using 900 MHz cordless phones? If you think the miniscule amount of "radiation" being emitted from a cell phone is bad, why put yourself at "risk" and use a cordless phone? It's the same radiation, it's in the same place.

Of course I'm sure there are people out there who walk around wrapped up in fine metal mesh clothing all day, to make sure none of the nasty 'radiation' skipping about the ionosphere doesn't get near you. You don't use anything electric, because the theoretical EM "radiation/whatever" may kill you.

Oh! And how about all you who stay away from the cell phones AND the cordless phones, you must be using a computer to type messages to the newsgroup! What about the dangers of those 1 GHz processors? How come nobody's raised radiation issues about them? Oh, you may say "it's not enough radiation, and it's in a metal box anyway," but that'd be using the same excuse that cellular users work.

MY GOD, how many people use TV remotes? That little infrared LED on the end could cause cancer...just think of how many people have their remote control pointed at their leg...and then they bump a button! THEY COULD DIE!

The only real excuse to use is "there is no risk" but nobody can say that for sure on the sole note that there MAY be some connection to cancer or disease and until we rule out that 1/1,000,000,000 chance, you can't say no because then you'd be wrong, and these days, wrong is not good ;) .

Honestly, I do believe we have more pressing matters at hand, like making sure we actually get a president elected! ;) (I do know that it's finally Bush, but still, for sake of example.)

Next month: "cosmic rays" in aircraft? Should you never fly in an airplane because of them? and, a new feature story "My toaster oven killed my husband." See how the evil heat radiation can destroy a family.

::sigh::....

Source record: 174434

Hello amigos,

I've recently moved to a hilltop in northwestern NJ and have been experimenting
with DXing on 80m. I'd like to hear what types of antennas others in the area use on this band. My reason for asking concerns my own dilemma:

The first antenna I tried on this band was a 67' wire vertical with 3 1/4-wave on-the-ground radials. Performance was terrible. I know 3 radials isn't enough, but I should have had some success. Couldn't cross the Atlantic. Then I put up a dipole at about 50 feet and now have almost a dozen European/African countries on the band. But there are still times when I hear a DX station who is 57 or 579 calling CQ. I answer and get no reply - he calls CQ again, never hearing me. I'm running 100 watts.

I know verticals are favored for low angle radiation on the low bands and wonder if more radials would have helped? I also know that a verticals' performance is highly dependant on the conductivity of the ground several wavelengths beyond the length of the radials. Is the nature of the soil conductivity in this part of the state such that horizontally polarized antennas are a better choice? If so, my plans are to install another dipole parallel to my current one to act as a parasitic reflector.

Thanks for any help/suggestions/ideas or donations of 80m Yagis!
73 and happy holidays,

John Harper AE5X

Gray Frierson Haertig wrote:
" Modern AM construction generally tries to avoid air dielectric variables (though I have quite a collection taken out of old installations when rebuilt) because of their tendency to change values when the spiders, wasps, and mice move in."

That is a commendable change. I`ve cleaned up after the beasties in broadcast networks. My AM experience was with roller inductors and air variable capacitors in the medium wave band. In the short wave bands, the equipment was full of vacuum variables. I attributed that to the fewer micromikes required and the 100 KW power outputs. Reduced maintenance is a nice result that should be considered more often.

Best regards, Richard Harrison, KB5WZI

I have noticed the fiberglass base insulator in my R7 is starting to "fuzz", apparently from UV exposure. Have Krylon plastikote, clear lacquer and Scotch Electrical coating. Any idea which will be best to use on it? Thanks!

Exactly. I live in Westchester County, NY, and yes there are
also a number of very rich people here (although I am not sure
that this is the case in the example I cited). Rich people who
hire lawyers for recreation when they see something being done
in a nearby town that they do not like. It's called the NIMBY
syndrome -- Not In My BackYard. Currently, they are fighting a
proposed IKEA. The people in the immediate area where they want
to build it are complaining, but I think it's mainly the
neighboring towns who claim that they will get more traffic but
not the tax benefit from it.

I can tell others stories, like everyone who sued to prevent the
airport from being expanded, including the neighboring (and very
affluent) town of Greenwich, CT, when it turns out that a large
percentage of the airport users (especially the corporate jet
users) are from, you guessed it, Greenwich.

Similar experience here. When mobiling, 80 and 40 get out equally well whether I'm out in the open or down in a valley. On 20 I begin to notice the valley effect; on 15 and 10 it is quite pronounced. Above that it's almost line of sight.

I've seen these Russian standards quoted before. And I've always wondered if they were actually enforced, or just published for propaganda purposes ("Look what good care we take of our people!"). Based on the record of Soviet environmental disasters, I strongly suspect the latter. Do you really suppose that Russian microwave ovens, for example, are much better shielded and sealed than ones sold in the U.S.? Or that the level of exposure of people living near the cold war jamming transmitters was really below these levels?

Disconnect the rod. You want as little as possible of your RF energy flowing through dirt. If at all possible, move the whole thing up as high as you can. With only a couple of radials, you will still have a large portion of the return current flowing through the earth and the earth is very lossy for RF. Salt water would be ok, but plain dirt just gets warmed up.

If my thinking is wrong on this, someone please correct me.

I'd leave the ground rod, just for lightning protection.

If the gentleman has adequate radials, on the ground or elevated. I would
think there should be minimal RF current through the ground rod.

Can a ground rod "steal" RF current from a vertical with an adequate radial
system? If there is RF current flowing into the rod, I would assume it is
contributing something to the antenna efficency, despite the inadequate
number of radials.

Cheers

Peter

With a little modification, you could improve the performance on the other bands. The top section uses standard 3/8X24 threads. You could make your improvments there, by swapping in something with more (electrical) length.

Scott.

4301. Impedance of PL-259 and "Barrel" connector?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-16 05:53:46 UTC
From: Scott McClements <yetbbwa@grove.iup.edu>
Message-ID: <3A3B036A.1AF6A829@grove.iup.edu>
Source record: 174449

From what I understand, the characteristic impedance of coax is determined by the distance of the inner conductor to the outer conductor. So, what is the impedance of the PL-259 and the "Barrel" connector (whatever the number is on that thing)? Are they suppose to have a characteristic impedance of 50 ohms? Something to ponder at 12:52 am.

Scott.

John,
There is no single antenna that will be the 'best' for
DX'ing on 80 meters. By the very nature of propagation,
at times, a vertical will perform 'better' than some type
of horizontal antenna, and vis-a-versa. On the average,
the old saying about having lots of metal, high in the air,
is still true...

The PL-259 and other connectors of the "UHF" series are non-constant impedance connectors. The resulting mismatch is of negligible significance at the lower HF frequencies and they are even usable in many circumstances up to about 150 MHz. The manufacturers use them for the simplest reason -- they are CHEAP! I replace "UHF" connectors whenever conveniently possible with N, TNC or BNC connectors and always buy equipment with N connectors if there is the choice.

I spent a number of years working with UHF gear in the 450-470 mhz
region that all used UHF/PL259-SO239 style connectors of good quality,
installed at the General Electric factory. Never had a hint of a problem
from it and all equipment operated at rated output power an receiver
sensitivity. The impedence bump introduced by the connectors is
completely tolerable through 500mHz.

Dick

That's almost true, except for one word: "completely". It isn't quite
that clear-cut.

The impedance bump from a single 'UHF' connector is almost always
tolerable through 500MHz, except in special circumstances like test
equipment.

It becomes less tolerable if there are several of these connectors at
various places along a transmission line, causing reflections at a
variety of phase angles due to the lengths of the line segments.
Murphy's Law says that those small, "completely tolerable" reflections
are going to add rather than cancel. For example, you may find that the
SWR has crept up to around 2, which will start to activate the SWR

shutdown on some transmitters. This can be very difficult to trouble-shoot, because every line segment will test out OK. Since the only thing left untested is the antenna, the next thing is to climb the tower... only to discover there's nothing wrong up there either. Changing to constant impedance connectors such as N and BNC can be a complete cure.

Unfortunately N and BNC fall short in power handling at UHF. BNC drops out of the race because it will only accept small cables which get hot, soften and break down. N connectors are limited by the small center pin and the possibilities for misalignment. Above 1kW on 432MHz, they are right on the edge - if they're not absolutely perfect, you find out very quickly! On the other hand, 'UHF' connectors are reported to be good for many kW up to at least 50MHz.

Hummm, this was the idea behind me trying slightly elevated radials on my 160 inv-L. But I also kept a rod connection and also a few shorter radials layed on the ground. I tried them first on the ground, and then about 2 ft off the ground, which they still are at this time. I stayed connected the rod with both tries. I really couldn't tell much difference that I could notice so far. Maybe I should give it a try with all disconnected except the two elevated radials just to see what it does. I noticed a post where Tom mentioned that if the antenna is large/full size , then elevating the radials doesn't do too much, and so far my tries seem to support that, but I didn't try with the rod unhooked. I'll have to try that just for kicks. My thoughts so far was that it's best to have as much hooked up as possible, including a rod. And also like another poster, I like having the rod as a lightning return. I'll try a few tests this weekend if I can scrounge up a local to give me ground wave reports. I'm curious the difference. Right now, I have the two low elevated 1/4 wl radials, about 5 appx 1/8 wl radials on the ground, a rod, and tied into the mast ground system also which leads across the yard to the mast. The inv-l tree limb supported. My intitial thought was it would be better to add the rest of the ground to the radials, rather than use them alone...Time for a test I guess. MK

What time of year did you have the vertical up? It wasn't summer was it? I would think the 67 ft vertical would have done ok even with 3 radials. But that is just a bare min. I would think with more radials it could be pretty good. But also the idea of the phased array might do ok also. It would sure give you a boost in that direction." I've tried those on 40m and worked pretty well". But you will still have the fairly high angle of radiation of the single dipole. That won't change if the antenna is still at the same height. You might try both, the array and a replay of a vertical. Maybe with the decreasing noise on 80m, the vertical might fare better now. MK

The Ground Rod will make very little difference in RF performance, Leave it.
and put out a minimum of 16 radials , they do not have to be cut
for each band as the ground will detune them anyway.. I would just put out
16 cut for 40m if i could and put down another 16 in between cut for 20m. I
did this when I had my 4Btv ground mounted worked pretty good. You'll most
likely have to retune the antenna some after you install the radials.
Good Luck,
DAVE KC1DI

There's far too much importance attached to the 'high' and
'low' angle radiation from simple horizontal dipoles and
simple verticals. There's no sharp beam from either of them
at any elevation angle or direction.

In fact, at the general purpose elevation angle of 45
degrees, they radiate with equal strengths and there's
nothing to choose between them at angles, say, between 25
and 65 degrees, where most of the contacts lie.

And if anyone should mention a difference in 'gain' of N
decibels I shall scream and scream and scream.

Reg.

There are some antennas, that are quite inconspicuous, when
mounted on top of a street light pole. With the equipment
buried at the base, these installations are all but
invisible.

That's just an urban legend. ;-)

Actually, you should read some Carl Sagan books on the
probabilities of various things. He's quite good at
debunking a lot of things, while showing that others may
indeed be possible or even likely.

Radio Works is offering an MFJ-914 Auto-tuner Range Extender

Here's what they say:

"Now you can use your automatic tuner with most of our antennas. Previously we recommended using only manual tuners. Now, with the MFJ-914, you can extend the range of auto-tuner by a factor of up to 10:1. There is just one multi-position switch on the "914" that you set when you change bands. That's all there is to it. It's a wonderful solution to a real problem with auto-tuners. Best of all the price is only $57.95.

Has anybody used one. Sounds like a terrific solution if it works well.

Thanks,

Dodge N3HUO

Depends on the type of dielectric- and because the transition is not a
smooth one, it varies. Pretty much a don't care situation up through 70cM.

> ---
> Reg.

Sure, I agree overall, but he wants to work dx. I would think the
average dx to be under 20-25 degrees on 80m.
Just out of curiosity I ran a dipole and a vertical with 32 radials thru
the puter mill. The dipole at 50 ft on 80m had a gain of 1 dbi at appx
19-20 degrees. Less than that angle , lower than 1.0 dbi. The vertical
with 32 radials over average ground gave 1 dbi at 14 degrees. At the
19-20 degree angle that the dipole gave 1 dbi, the vertical almost gives
2.0 dbi nearly. With maximum at 24 degrees, compared to the dipoles max
at 90 degrees. But, you may ask, does it really matter? After all 1 db
isn't much at all, less than an s unit. But it seems to here. All of my
best low band dx antennas have been a vertical or some form of vertical.
And the difference seen in reports is not small. I'll spare you the db
gain stories, but 2+ s units difference is about the norm in the real
world on average real world s meters. Dunno, but I think the
polarization itself has as much to do with it as any gain at certain
angles. With all the refraction and scattering of the signal, that
shouldn't really matter, but the verticals seem to do better overall to
dx. Even over a high dipole many times. MK

Wouldn't these have a very limited range, because most streetlight poles
are not as tall as a typical cell tower?

I live on a boat on
the ICW down in SC 90% of the year and have a terrible time with efficient HF
antennas. I have been looking for a Hy-Gain HA-4000 tape measure antenna
for years but have never even come close. Being on the boat limits my ability
to really look. Would you have ANY suggestions or leads that might help me in
this endeavor? I currently use a Hustler mobil system on the bow railing and
have
had a plate welded on so that I can put a screwdriver on, but when I am
anchored
in small creeks it would be SO EASY to put up a tape measure for a more
effective
antenna. I would really appreciate any help you could provide.

Since toilet roll tubes are sometimes hard to come by in
Texas, will corn cobs do? :-)

Actually Reg, all one needs is five lengths of ladder-line.
Lengths of 2%, 4%, 8%, 16%, and 32% of a wavelength will
allow one to vary the feedline by 0-0.5WL thus making
one's autotuner happy and often not requiring an antenna
tuner at all.

The SGC-230 autotuner is designed for such a purpose. You could have
a 20ft whip which will work pretty well on 40m-10m. When you want a
better signal on 75m, attach a longer wire and throw it into a tree.

Ian brings up a good point. Microwave designers are especially worried about
this because the phase angle is rotating so quickly that even just two
reflections separated by a short distance can cause wild VSWR ripple as the
frequency is swept. Add a couple of more reflections by inserting another
device in a cascade and you quickly have a mess.

The worst case VSWR (all reflections in phase) is the product of the individual
VSWRs. So even at VHF, there can be a problem, if for instance, you have a
system with an SWR bridge or power meter in the line, followed by a filter,
followed by a change-over relay.....

If each of these has a "UHF" connector or two with a 1.2:1 VSWR or worse, and
the cable lengths happen to be "wrong", you may have a problem.

>
>Unfortunately N and BNC fall short in power handling at UHF. BNC drops

>many kW up to at least 50MHz.

The key is proper alignment and pin depth setting. I once tested a couple of dozen cables for power handling capability at 10 GHz. These were flexible cables using SMA connectors and were for a space application. The requirements were 100W input with a 3:1 VSWR load for one hour at an ambient temperature of 90 deg. C. All of the cables survived without degradation.

What was remarkable was that to achieve the 3:1 VSWR load I used a length of 0.141" semi-rigid coax, with an SMA connector on one end and a short on the other. The majority of the length was coiled up and placed into a can of water outside the temperature chamber for cooling. The SMA connecter on this cable survived about thirty hours of abuse as did the isolator in the Watkins-Johnson 400 W TWTA.

Something to not be overlooked when using UHF connectors is the ghastly assembly problem. It is easy to melt the dielectric when soldering the braid, to the point that the power handling capability is reduced.

At 160 meters, two feet off the ground is such a small fraction of a wavelength that it would make virtually no difference. May as well leave them directly on the ground. Please understand, when you have so many radials that the antenna does not "see" the actual earth, then leaving them on the ground is ok. It's only when you have just a few radials that elevating them up high would reduce ground losses. Something around ~120 radials qualifies as near-perfect.

This subject comes up periodically and there are always differing opinions. The N, TNC and BNC connectors have their advantages, but they have one disadvantage too - they are mechanically weaker than the PL-259 type and have a lower power rating, especially at VHF. The N connector in particular has an annoying habit of having the center conductor pull out of it's mate at a most inopportune time. I understand there are versions available which do a better job of locking it in place, so be sure to get one of those if you think that's a concern.

PL-259s work fine for most applications and the low cost, simplicity and universality of them is good enough for me and lots of other folks.

The PCS cell range is very small anyway. In an urban area there are probably cases where they just need to fill in some gaps between tall buildings. In Baltimore, they have a small tower at each end of a tunnel with antennas pointing into the tunnel to get coverage inside.

Along Route 95 in Maryland there are some very tall light poles at some interchanges. They must be 150 feet tall! I've notice cell phone antennas there too. Offhand, I don't recall whether or not they're free-standing or on light poles.

Better yet, go to:

www.joshmadison.com/software

And download a free conversion program that will do it for you. This incredible little program converts practically anything - not just metric/English - and is totally free. Best bargain in town! Windows 32 bit only, sorry, (no Win 3.1).

I did a search through rec.radio.swap and found nothing. Must be pretty rare indeed. Sorry.

I can't help saying that in the States, 1" is exactly 2.54 cm because that is our legal definition of an inch. (Kinda makes me wonder why some Americans seem to have so much trouble with the Metric system.)

Great work. I knew the various standards varied, but I didn't know that there was that much difference.
